

Package ‘VariantAnnotation’

October 9, 2013

Type Package

Title Annotation of Genetic Variants

Description Annotate variants, compute amino acid coding changes, predict coding outcomes

Version 1.6.8

Author Valerie Obenchain, Martin Morgan, Michael Lawrence with contributions from Stephanie Gogarten.

filterVcf	<i>Filter VCF files</i>
-----------	-------------------------

Description

Filter Variant Call Format (VCF) files from one file to another

Usage

```
## S4 method for signature 'character'
filterVcf(file, genome, destination, ..., verbose = TRUE,
          index = FALSE, prefilters = FilterRules(), filters = FilterRules(),
          param = ScanVcfParam())
```

```
## S4 method for signature 'TabixFile'
filterVcf(file, genome, destination, ..., verbose = TRUE,
          index = FALSE, prefilters = FilterRules(), filters = FilterRules(),
          param = ScanVcfParam())
```

Arguments

file	A character(1) file path or TabixFile specifying the VCF file to be filtered.
genome	A character(1) identifier
destination	A character(1) path to the location where the filtered VCF file will be written.
...	Additional arguments, possibly used by future methods.
verbose	A logical(1) indicating whether progress messages should be printed.

index	A logical(1) indicating whether the filtered file should be compressed and indexed (using bgzip and indexTabix).
prefilters	A FilterRules instance contains rules for filtering un-parsed lines of the VCF file.
filters	A FilterRules instance contains rules for filtering fully parsed VCF objects.
param	A ScanVcfParam instance restricting input of particular info or geno files, or genomic locations.

Details

This function transfers content of one VCF file to another, removing records that fail to satisfy [prefilters](#) and [filters](#). Filtering is done in a memory efficient manner, iterating over the input VCF file in chunks of default size 100,000 (when invoked with [character\(1\)](#) for file) or as specified by the [yieldSize](#) argument of [TabixFile](#) (when invoked with [TabixFile](#)).

There are up to two passes. In the first pass, unparsed lines are passed to [prefilters](#) for filtering, e.g., searching for a fixed character string. In the second pass lines successfully passing [prefilters](#) are parsed into VCF instances and made available for further filtering. One or both of [prefilter](#) and [filter](#) can be present.

Value

The destination file path as a [character\(1\)](#).

Author(s)

Martin Morgan <mailto:mtmorgan@fhcrc.org> and Paul Shannon <mailto:pshannon@fhcrc.org>.

[readVcf](#), [writeVcf](#).

Examples

```
f1 <- system.file(package="VariantAnnotation", "extdata",
                 "chr22.vcf.gz")
destination <- tempfile()
pre <- FilterRules(list(isLowCoverageExomeSnp = function(x) {
  grepl("LOWCOV,EXOME", x, fixed=TRUE)
}))
filt <- FilterRules(list(isSNP = function(x) info(x)$VT == "SNP"))
filtered <- filterVcf(f1, "hg19", destination, prefilters=pre, filters=filt)
vcf <- readVcf(filtered, "hg19")
```

genotypeToSnpMatrix *Convert genotype calls from a VCF file to a SnpMatrix object*

Description

Convert an array of genotype calls from the "GT", "GP", or "GL" FORMAT field of a VCF file to a [SnpMatrix](#).

Usage

```
## S4 method for signature 'CollapsedVCF'
genotypeToSnpMatrix(x, uncertain=FALSE, ...)
## S4 method for signature 'array'
genotypeToSnpMatrix(x, ref, alt, ...)
```

Arguments

x	A CollapsedVCF object or a array of genotype data from the "GT", "GP", or "GL" FORMAT field of a VCF file. This array is created with a call to readVcf and can be accessed with geno(<VCF>).
uncertain	A logical indicating whether the genotypes to convert should come from the "GT" field (uncertain=FALSE) or the "GP" or "GL" field (uncertain=TRUE).
ref	A DNASTringSet of reference alleles.
alt	A DNASTringSetList of alternate alleles.
...	Additional arguments, passed to methods.

Details

genotypeToSnpMatrix converts an array of genotype calls from the "GT", "GP", or "GL" FORMAT field of a VCF file into a [SnpMatrix](#). The following caveats apply,

- no distinction is made between phased and unphased genotypes
- variants with >1 ALT allele are set to NA
- only single nucleotide variants are included; others are set to NA
- only diploid calls are included; others are set to NA

In VCF files, 0 represents the reference allele and integers greater than 0 represent the alternate alleles (i.e., 2, 3, 4 would indicate the 2nd, 3rd or 4th allele in the ALT field for a particular variant). This function only supports variants with a single alternate allele and therefore the alternate values will always be 1. Genotypes are stored in the SnpMatrix as 0, 1, 2 or 3 where 0 = missing, 1 = "0/0", 2 = "0/1" or "1/0" and 3 = "1/1". In SnpMatrix terminology, "A" is the reference allele and "B" is the risk allele. Equivalent statements to those made with 0 and 1 allele values would be 0 = missing, 1 = "A/A", 2 = "A/B" or "B/A" and 3 = "B/B".

The three genotype fields are defined as follows:

- GT : genotype, encoded as allele values separated by either of "/" or "|". The allele values are 0 for the reference allele and 1 for the alternate allele.
- GL : genotype likelihoods comprised of comma separated floating point log10-scaled likelihoods for all possible genotypes. In the case of a reference allele A and a single alternate allele B, the likelihoods will be ordered "A/A", "A/B", "B/B".
- GP : the phred-scaled genotype posterior probabilities for all possible genotypes; intended to store imputed genotype probabilities. The ordering of values is the same as for the GL field.

If uncertain=TRUE, the posterior probabilities of the three genotypes ("A/A", "A/B", "B/B") are encoded (approximately) as byte values. This encoding allows uncertain genotypes to be used in [snpStats](#) functions, which in some cases may be more appropriate than using only the called genotypes. The byte encoding conserves memory by allowing the uncertain genotypes to be stored in a two-dimensional raw matrix. See the [snpStats](#) documentation for more details.

Value

A list with the following elements,

genotypes	The output genotype data as an object of class "SnpMatrix". The columns are snps and the rows are the samples. See ?SnpMatrix details of the class structure.
map	A DataFrame giving the snp names and alleles at each locus. The ignore column indicates which variants were set to NA (see NA criteria in 'details' section).

Examples

```
## -----
## Non-probability based snp encoding using "GT"
## -----
fl <- system.file("extdata", "ex2.vcf", package="VariantAnnotation")
vcf <- readVcf(fl, "hg19")

## This file has no "GL" or "GP" field so we use "GT".
geno(vcf)

## Convert the "GT" FORMAT field to a SnpMatrix.
mat <- genotypeToSnpMatrix(vcf)

## The result is a list of length 2.
```

```

names(mat)

## Compare coding in the VCF file to the SnpMatrix.
geno(vcf)$GT
t(as(mat$genotype, "character"))

## The 'ignore' column in 'map' indicates which variants
## were set to NA. Variant rs6040355 was ignored because
## it has multiple alternate alleles, microsata1 is not a
## snp, and chr20:1230237 has no alternate allele.
mat$map

## -----
## Probability-based encoding using "GL" or "GP"
## -----
## Read a vcf file with a "GL" field.
fl <- system.file("extdata", "gl_chr1.vcf", package="VariantAnnotation")
vcf <- readVcf(fl, "hg19")
geno(vcf)

## Convert the "GL" FORMAT field to a SnpMatrix
mat <- genotypeToSnpMatrix(vcf, uncertain=TRUE)

## Only 3 of the 9 variants passed the filters. The
## other 6 variants had no alternate alleles.
mat$map

## Compare genotype representations for a subset of
## samples in variant rs180734498.
## Original called genotype
geno(vcf)$GT["rs180734498", 14:16]

## Original genotype likelihoods
geno(vcf)$GL["rs180734498", 14:16]

## Posterior probability (computed inside genotypeToSnpMatrix)
GLtoGP(geno(vcf)$GL["rs180734498", 14:16, drop=FALSE])[1,]

## SnpMatrix coding.
t(as(mat$genotype, "character"))["rs180734498", 14:16]
t(as(mat$genotype, "numeric"))["rs180734498", 14:16]

## For samples NA11829 and NA11830, one probability is significantly
## higher than the others, so SnpMatrix calls the genotype. These
## calls match the original coding: "0|1" -> "A/B", "0|0" -> "A/A".
## Sample NA11831 was originally called as "0|1" but the probability
## of "0|0" is only a factor of 3 lower, so SnpMatrix calls it as
## "Uncertain" with an appropriate byte-level encoding.

```

Description

Extract transcript sequences from a [BSgenome](#) object or an [FaFile](#).

Usage

```
## S4 method for signature 'GRangesList,BSgenome'  
getTranscriptSeqs(query, subject, ...)  
## S4 method for signature 'GRangesList,FaFile'  
getTranscriptSeqs(query, subject, ...)  
## S4 method for signature 'GRanges,FaFile'  
getTranscriptSeqs(query, subject, ...)
```

Arguments

query	A GRangesList object containing exons or cds grouped by transcript.
subject	A BSgenome object or a FaFile from which the sequences will be taken.
...	Additional arguments

Details

getTranscriptSeqs is a wrapper for the extractTranscriptsFromGenome and getSeq functions. The purpose is to allow sequence extraction from either a [BSgenome](#) or [FaFile](#). Transcript sequences are extracted based on the boundaries of the feature provided in the query (i.e., either exons or cds regions).

Value

A [DNASTringSet](#) instance containing the sequences for all transcripts specified in query.

Author(s)

Valerie Obenchain

Examples

```
library(TxDb.Hsapiens.UCSC.hg19.knownGene)  
library(BSgenome.Hsapiens.UCSC.hg19)  
  
txdb <- TxDb.Hsapiens.UCSC.hg19.knownGene  
cdsByTx <- cdsBy(txdb)  
chr20 <- keepSeqlevels(cdsByTx, "chr20")  
  
## BSgenome as sequence source  
bsSource <- getTranscriptSeqs(chr20, Hsapiens)
```

GLtoGP

Convert genotype likelihoods to genotype probabilities

Description

Convert an array of genotype likelihoods to posterior genotype probabilities.

Usage

```
GLtoGP(gl)
```

Arguments

`gl` Array of genotype likelihoods. The format can be a matrix of lists, or a three-dimensional array in which the third dimension corresponds to the probabilities for each genotype.

Details

Computes the probability of each genotype as $10^x / \text{sum}(10^x)$.

Value

An array of posterior genotype probabilities, in the same format as the input (matrix of lists or 3D array).

Author(s)

Stephanie Gogarten <sdmorris@u.washington.edu>

Examples

```
## Read a vcf file with a "GL" field.
vcfFile <- system.file("extdata", "gl_chr1.vcf", package="VariantAnnotation")
vcf <- readVcf(vcfFile, "hg19")

## extract genotype likelihoods as a matrix of lists
gl <- geno(vcf)$GL
class(gl)
mode(gl)

# convert to posterior probabilities
gp <- GLtoGP(gl)
```

locateVariants	<i>Locate variants</i>
----------------	------------------------

Description

Variant location with respect to gene function

Usage

```
locateVariants(query, subject, region, ...)
## S4 method for signature 'VCF,TranscriptDb,VariantType'
locateVariants(query, subject, region, ..., cache=new.env(parent=emptyenv()), ignore.strand=FALSE, asHits=FALSE)
## S4 method for signature 'GRanges,TranscriptDb,VariantType'
locateVariants(query, subject, region, ..., cache=new.env(parent=emptyenv()), ignore.strand=FALSE, asHits=FALSE)
```

Arguments

query	A Ranges , GRanges or VCF object containing the variants. Metadata columns are allowed but are ignored. NOTE: Circular chromosomes are not currently supported.
subject	A TranscriptDb or GRangesList object that serves as the annotation. GFF files can be converted to TranscriptDb objects with <code>makeTranscriptDbFromGFF()</code> in the GenomicFeatures package.
region	An instance of one of the 8 VariantType classes: <code>CodingVariants</code> , <code>IntronVariants</code> , <code>FiveUTRVariants</code> , <code>ThreeUTRVariants</code> , <code>IntergenicVariants</code> , <code>SpliceSiteVariants</code> , <code>PromoterVariants</code> , <code>AllVariants</code> . All objects are instantiated with no arguments, e.g., <code>CodingVariants()</code> will create an object of <code>CodingVariants</code> . <code>AllVariants</code> and <code>PromoterVariants</code> classes can be given upstream and downstream arguments.
...	Additional arguments passed to methods
cache	An environment into which required components of subject are loaded. Provide, and re-use, a cache to speed repeated queries to the same subject across different query instances.
ignore.strand	A logical indicating if strand should be ignored when performing overlaps.
asHits	A logical indicating if the results should be returned as a Hits object. Not applicable when region is <code>AllVariants</code> or <code>IntergenicVariants</code> .

Details

Range representation : The ranges in query should reflect the position(s) of the reference allele. For snps the range will be of width 1. For range insertions or deletions the reference allele could be a sequence such as GGTG in which case the width of the range should be 4.

Location : Possible locations are 'coding', 'intron', 'threeUTR', 'fiveUTR', 'intergenic', 'splice-Site', or 'promoter'.

Overlap operations for ‘coding’, ‘intron’, ‘threeUTR’, and ‘fiveUTR’ require variants to fall completely within the defined region to be classified as such.

To be classified as a ‘spliceSite’ the variant must overlap with any portion of the first 2 or last 2 nucleotides in an intron.

‘intergenic’ variants are those that do not fall within a transcript associated with a gene. If available, gene IDs for the flanking genes are give as the PRECEDEID and FOLLOWID.

‘promoter’ variants fall within a specified range upstream and downstream of the transcription start site. Ranges values can be set with the upstream and downstream arguments when creating the PromoterVariants() or AllVariants() classes.

Subject as GRangesList : The subject can be a TranscriptDb or GRangesList object. When using a GRangesList the type of data required is driven by the VariantType class. Below is a description of the appropriate GRangesList for each VariantType.

CodingVariants : coding (CDS) by transcript

IntronVariants : introns by transcript

FiveUTRVariants : five prime UTR by transcript

ThreeUTRVariants : three prime UTR by transcript

IntergenicVariants : transcripts by gene

SpliceSiteVariants : introns by transcript

PromoterVariants : list of transcripts

AllVariants : no GRangesList method available

Using the cache : When processing multiple VCF files performance is enhanced by specifying an environment as the cache argument. This cache is used to store and reuse extracted components of the subject (TxDb) required by the function. The first call to the function (i.e., processing the first VCF file in a list of many) populates the cache; repeated calls to locateVariants will access these objects from the cache vs re-extracting the same information.

Value

A GRanges object with a row for each variant-transcript match. Columns are LOCATION, QUERYID, TXID, GENEID, PRECEDEID, FOLLOWID and CDSID. Each column is described in detail below.

LOCATION Possible locations are ‘coding’, ‘intron’, ‘threeUTR’, ‘fiveUTR’, ‘intergenic’, ‘spliceSite’ and ‘promoter’.

To be classified as ‘coding’, ‘intron’, ‘threeUTR’ or ‘fiveUTR’ the variant must fall completely within the region.

‘intergenic’ variants do not fall within a transcript. The ‘GENEID’ for these position are NA and instead the ‘PRECEDEID’ and ‘FOLLOWID’ for the flanking genes are given.

A ‘spliceSite’ variant overlaps any portion of the first 2 or last 2 nucleotides of an intron.

QUERYID The QUERYID column provides a map back to the row in the original query. If the query was a VCF object this index corresponds to the row in the GRanges in the rowData slot.

TXID The transcript id taken from the TranscriptDb object.

CDSID The coding sequence id taken from the TranscriptDb object.

GENEID The gene id taken from the TranscriptDb object.

PRECEDEID The id of the gene the query precedes. Only present for ‘intergenic’ variants.

FOLLOWID The id of the gene the query follows. Only present for ‘intergenic’ variants.

All ID values will be ‘NA’ for variants with a location of transcript_region or NA.

MatrixToSnpMatrix

Convert genotype calls from a VCF file to a SnpMatrix object

Description

This method is deprecated. Use [genotypeToSnpMatrix](#) instead.

Convert a matrix of genotype calls from the "GT" FORMAT field of a VCF file to a [SnpMatrix](#).

Usage

```
MatrixToSnpMatrix(callMatrix, ref, alt, ...)
```

Arguments

callMatrix	A matrix of genotype data from the "GT" FORMAT field of a VCF file. This matrix is created with a call to readVcf and can be accessed with <code>geno<VCF></code> .
ref	A DNASTringSet of reference alleles.
alt	A DNASTringSetList of alternate alleles.
...	Additional arguments, passed to methods.

Details

MatrixToSnpMatrix converts a matrix of genotype calls from the "GT" FORMAT field of a VCF file into a [SnpMatrix](#). The following caveats apply,

- no distinction is made between phased and unphased genotypes
- only diploid calls are included; others are set to NA
- only single nucleotide variants are included; others are set to NA
- variants with >1 ALT allele are set to NA

In VCF files, 0 represents the reference allele and integers greater than 0 represent the alternate alleles (i.e., 2, 3, 4 would indicate the 2nd, 3rd or 4th allele in the ALT field for a particular variant). This function only supports variants with a single alternate allele and therefore the alternate values will always be 1. Genotypes are stored in the SnpMatrix as 0, 1, 2 or 3 where 0 = missing, 1 = "0/0", 2 = "0/1" or "1/0" and 3 = "1/1". In SnpMatrix terminology, "A" is the reference allele and "B" is the risk allele. Equivalent statements to those made with 0 and 1 allele values would be 0 = missing, 1 = "A/A", 2 = "A/B" or "B/A" and 3 = "B/B".

Value

A list with the following elements,

genotypes	The output genotype data as an object of class "SnpMatrix". The columns are snps and the rows are the samples. See the help page for SnpMatrix for complete details of the class structure.
map	A DataFrame giving the snp names and alleles at each locus. The ignore column indicates which variants were set to NA because they met one or more of the caveats stated above.

PolyPhenDb-class

PolyPhenDb objects

Description

The PolyPhenDb class is a container for storing a connection to a PolyPhen sqlite database.

Details

PolyPhen (Polymorphism Phenotyping) is a tool which predicts the possible impact of an amino acid substitution on the structure and function of a human protein by applying empirical rules to the sequence, phylogenetic and structural information characterizing the substitution.

PolyPhen makes its predictions using UniProt features, PSIC profiles scores derived from multiple alignment and matches to PDP or PQS structural databases. The procedure can be roughly outlined in the following steps, see the references for complete details,

- sequence-based characterization of substitution site

- calculation of PSIC profile scores for two amino acid variants
- calculation of structural parameters and contacts
- prediction

PolyPhen uses empirically derived rules to predict that a non-synonymous SNP is

- probably damaging : it is with high confidence supposed to affect protein function or structure
- possibly damaging : it is supposed to affect protein function or structure
- benign : most likely lacking any phenotypic effect
- unknown : when in some rare cases, the lack of data do not allow PolyPhen to make a prediction

Methods

In the code below, `x` is a PolyPhenDb object.

`metadata(x)`: Returns `x`'s metadata in a data frame.

`cols(x)`: Returns the names of the `cols` that can be used to subset the data columns. For column descriptions see `?PolyPhenDbColumns`.

`keys(x)`: Returns the names of the `keys` that can be used to subset the data rows. The `keys` values are the `rsid`'s.

`select(x, keys = NULL, cols = NULL, ...)`: Returns a subset of data defined by the character vectors `keys` and `cols`. If no `keys` are supplied, all rows are returned. If no `cols` are supplied, all columns are returned. See `?PolyPhenDbColumns` for column descriptions.

`duplicateRSID(x)`: Returns a named list of duplicate `rsid` groups. The names are the `keys`, the list elements are the `rsid`'s that have been reported as having identical chromosome position and alleles and therefore translating into the same amino acid residue substitution.

PolyPhenDbColumns

PolyPhenDb Columns

Description

Description of the PolyPhen Sqlite Database Columns

Column descriptions

These column names are displayed when `cols` is called on a PolyPhenDb object.

- `rsid` : rsid

Original query :

- `OSNPID` : original SNP identifier from user input
- `OSNPACC` : original protein identifier from user input
- `OPOS` : original substitution position in the protein sequence from user input
- `OAA1` : original wild type (reference) aa residue from user input
- `OAA2` : original mutant (reference) aa residue from user input

Mapped query :

- SNPID : SNP identifier mapped to dbSNP rsID if available, otherwise same as o_snp_id. This value was used as the rsid column
- ACC : protein UniProtKB accession if known protein, otherwise same as o_acc
- POS : substitution position mapped to UniProtKB protein sequence if known, otherwise same as o_pos
- AA1 : wild type aa residue
- AA2 : mutant aa residue
- NT1 : wild type allele nucleotide
- NT2 : mutant allele nucleotide

PolyPhen-2 prediction :

- PREDICTION : qualitative ternary classification FPR thresholds

PolyPhen-1 prediction :

- BASEDON : prediction basis
- EFFECT : predicted substitution effect on the protein structure or function

PolyPhen-2 classifiers :

- PPH2CLASS : binary classifier outcome ("damaging" or "neutral")
- PPH2PROB : probability of the variation being damaging
- PPH2FPR : false positive rate at the pph2_prob level
- PPH2TPR : true positive rate at the pph2_prob level
- PPH2FDR : false discovery rate at the pph2_prob level

UniProtKB-SwissProt derived protein sequence annotations :

- SITE : substitution SITE annotation
- REGION : substitution REGION annotation
- PHAT : PHAT matrix element for substitution in the TRANSMEM region

Multiple sequence alignment scores :

- DSCORE : difference of PSIC scores for two aa variants (Score1 - Score2)
- SCORE1 : PSIC score for wild type aa residue (aa1)
- SCORE2 : PSIC score for mutant aa residue (aa2)
- NOBS : number of residues observed at the substitution position in the multiple alignment (sans gaps)

Protein 3D structure features :

- NSTRUCT : initial number of BLAST hits to similar proteins with 3D structures in PDB
- NFILT : number of 3D BLAST hits after identity threshold filtering
- PDBID : protein structure identifier from PDB

- PDBPOS : position of substitution in PDB protein sequence
- PDBCH : PDB polypeptide chain identifier
- IDENT : sequence identity between query and aligned PDB sequences
- LENGTH : PDB sequence alignment length
- NORMACC : normalized accessible surface
- SECSTR : DSSP secondary structure assignment
- MAPREG : region of the phi-psi (Ramachandran) map derived from the residue dihedral angles
- DVOL : change in residue side chain volume
- DPROP : change in solvent accessible surface propensity resulting from the substitution
- BFACT : normalized B-factor (temperature factor) for the residue
- HBONDS : number of hydrogen sidechain-sidechain and sidechain-mainchain bonds formed by the residue
- AVENHET : average number of contacts with heteroatoms per residue
- MINDHET : closest contact with heteroatom
- AVENINT : average number of contacts with other chains per residue
- MINDINT : closest contact with other chain
- AVENSIT : average number of contacts with critical sites per residue
- MINDSIT : closest contact with a critical site

Nucleotide sequence features (CpG/codon/exon junction) :

- TRANSV : whether substitution is a transversion
- CODPOS : position of the substitution within the codon
- CPG : whether or not the substitution changes CpG context
- MINDJNC : substitution distance from exon/intron junction

Pfam protein family :

- PFAMHIT : Pfam identifier of the query protein

Substitution scores :

- IDPMAX : maximum congruency of the mutant aa residue to all sequences in multiple alignment
- IDPSNP : maximum congruency of the mutant aa residue to the sequence in alignment with the mutant residue
- IDQMIN : query sequence identity with the closest homologue deviating from the wild type aa residue

predictCoding

Predict amino acid coding changes for variants

Description

Predict amino acid coding changes for variants a coding regions

Usage

```
## S4 method for signature 'CollapsedVCF,TranscriptDb,ANY,missing'
predictCoding(query, subject, seqSource, varAllele, ..., ignore.strand=FALSE)
## S4 method for signature 'ExpandedVCF,TranscriptDb,ANY,missing'
predictCoding(query, subject, seqSource, varAllele, ..., ignore.strand=FALSE)
## S4 method for signature 'Ranges,TranscriptDb,ANY,DNAStringSet'
predictCoding(query, subject, seqSource, varAllele, ..., ignore.strand=FALSE)
## S4 method for signature 'GRanges,TranscriptDb,ANY,DNAStringSet'
predictCoding(query, subject, seqSource, varAllele, ..., ignore.strand=FALSE)
```

Arguments

query	A VCF , Ranges or GRanges instance containing the variants to be annotated. If a Ranges is provided it will be coerced to a GRanges . If a VCF is provided the GRanges from the <code>rowData</code> slot will be used. All <code>elementMetadata</code> columns are ignored. When the query is not a VCF object a <code>varAllele</code> must be provided. The <code>varAllele</code> must be a DNAStringSet the same length as the query. If there are multiple alternate alleles per variant the query must be expanded to one row per each alternate allele. See examples.
subject	A TranscriptDb object that serves as the annotation. GFF files can be converted to TranscriptDb objects with <code>makeTranscriptDbFromGFF()</code> in the <code>GenomicFeatures</code> package.
seqSource	A BSgenome instance or an FaFile to be used for sequence extraction.
varAllele	A DNAStringSet containing the variant (alternate) alleles. The length of <code>varAllele</code> must equal the length of query. Missing values are represented by a zero width empty element. Ranges with missing <code>varAllele</code> values are ignored; those with an 'N' character are not translated. When the query is a VCF object the <code>varAllele</code> argument will be missing. This value is taken internally from the VCF with <code>alt(<VCF>)</code> .
...	Additional arguments passed to methods.
ignore.strand	A logical indicating if strand should be ignored when performing overlaps.

Details

This function returns the amino acid coding for variants that fall completely ‘within’ a coding region. The reference sequences are taken from a fasta file or [BSgenome](#). The width of the reference is determined from the start position and width of the range in the query. For guidance on how to represent an insertion, deletion or substitution see the 1000 Genomes VCF format (references).

Variant alleles are taken from the `varAllele` when supplied. When the query is a VCF object the `varAllele` will be missing. This value is taken internally from the VCF with `alt(<VCF>)`. The variant allele is substituted into the reference sequences and transcribed. Transcription only occurs if the substitution, insertion or deletion results in a new sequence length divisible by 3.

When the query is an unstranded (*) GRanges `predictCoding` will attempt to find overlaps on both the positive and negative strands of the subject. When the subject hit is on the negative strand the return `varAllele` is reverse complemented. The strand of the returned GRanges represents the strand of the subject hit.

Value

A [GRanges](#) with a row for each variant-transcript match. The result includes only variants that fell within coding regions. If the query was unstranded (*) or `ignore.strand=TRUE` the strand of the output GRanges represents the strand of the subject hit.

At a minimum, the `elementMetadata` columns include,

`varAllele` Variant allele. This value is reverse complemented for an unstranded query that overlaps a subject on the negative strand.

`QUERYID` Map back to the row in the original query

`TXID` Internal transcript id from the annotation

`CDSID` Internal coding region id from the annotation

`GENEID` Internal gene id from the annotation

`CDSLOC` Location in coding region-based coordinates of the first nucleotide in the variant.

`PROTEINLOC` Location in cds-based coordinates of the first nucleotide in the variant. This position is relative to the start of the cds region defined in the subject annotation.

`CONSEQUENCE` Possible values are ‘synonymous’, ‘nonsynonymous’, ‘frameshift’, ‘nonsense’ and ‘not translated’. Variant sequences are translated only when the codon sequence is a multiple of 3. The value will be ‘frameshift’ when a sequence is of incompatible length and it will be ‘not translated’ when the `varAllele` is missing or there is an ‘N’ in the sequence. ‘nonsense’ is used for premature stop codons.

`REFCODON` The reference codon sequence. This range is typically greater than the width of the range in the GRanges because it includes all codons involved in the sequence modification. If the reference sequence is of width 2 but the alternate allele is of width 4 then at least two codons must be included in the REFSEQ.

`VARCODON` This sequence is the result of inserting, deleting or replacing the position(s) in the reference sequence alternate allele. If the result of this modification is not a multiple of 3 no translation is performed and the `VARAA` value will be missing.

`REEFAA` The reference amino acid column contains the translated REFSEQ.

`VARAA` The variant amino acid column contains the translated VARSEQ. When translation is not possible this value is missing.

Examples

```
library(BSgenome.Hsapiens.UCSC.hg19)
library(TxDb.Hsapiens.UCSC.hg19.knownGene)
txdb <- TxDb.Hsapiens.UCSC.hg19.knownGene

## -----
## VCF object as query
## -----
## Read variants from a VCF file
fl <- system.file("extdata", "chr22.vcf.gz", package="VariantAnnotation")
vcf <- readVcf(fl, "hg19")

## Rename seqlevels in the VCF object to match those in the TxDb
vcf<- renameSeqlevels(vcf, c("22"="chr22"))
## Confirm common seqlevels
intersect(seqlevels(vcf), seqlevels(txdb))

## Note when 'query' is a VCF object the varAllele argument is missing.
coding1 <- predictCoding(vcf, txdb, Hsapiens)
head(coding1, 3)

## -----
## GRanges object as query
## -----
## Alternatively, a GRanges can be the 'query' to predictCoding().
## The seqlevels were previously adjusted in the VCF object so the GRanges
## extracted from rowData() has the correct seqlevels.
rd <- rowData(vcf)

## The GRanges must be expanded to have one row per alternate allele.
## Variants 1, 2 and 10 have two alternate alleles.
altallele <- alt(vcf)
eltlen <- elementLengths(altallele)
rd_exp <- rep(rd, eltlen)

## Call predictCoding() with the expanded GRanges as the 'query'
## and the unlisted alternate allele as the 'varAllele'.
coding2 <- predictCoding(rd_exp, txdb, Hsapiens, unlist(altallele))

identical(coding1, coding2)
```

`probabilityToSnpMatrix`*Convert posterior genotype probability to a SnpMatrix object*

Description

Convert a matrix of posterior genotype probabilities P(AA), P(AB), P(BB) to a [SnpMatrix](#).

Usage

```
probabilityToSnpMatrix(probs)
```

Arguments

`probs` Matrix with three columns for the posterior probabilities of the three genotypes: "P(A/A)", "P(A/B)", "P(B/B)". Each row must sum to 1.

Details

`probabilityToSnpMatrix` converts a matrix of posterior probabilities of genotype calls into a [SnpMatrix](#).

Value

An object of class "SnpMatrix" with one row (one sample). Posterior probabilities are encoded (approximately) as byte values, one per SNP. See the help page for [SnpMatrix](#) for complete details of the class structure.

## S4 method for signature 'character,character,missing'
readVcf(file, genome, param, ...)
## S4 method for signature 'character,missing,missing'
readVcf(file, genome, param, ...)
```

Arguments

file	A TabixFile instance or character() name of the VCF file to be processed. When ranges are specified in param, file must be a TabixFile . Use of the TabixFile methods are encouraged as they are more efficient than the character() methods. See ?TabixFile and ?indexTabix for help creating a TabixFile .
genome	The character() name of the genome the variants are mapped to. This information is stored in the genome slot of the seqinfo associated with the GRanges object in rowData.
param	A instance of ScanVcfParam , GRanges , GRangesList , RangedData or RangesList . VCF files can be subset on genomic coordinates (ranges) or elements in the VCF fields. Both genomic coordinates and VCF elements can be specified in a ScanVcfParam . See ?ScanVcfParam for details.
...	Additional arguments, passed to methods.

Details

Data Import : VCF object : readVcf imports records from bzip compressed or uncompressed VCF files. Data are parsed into a [VCF](#) object using the file header information if available. To import a subset of ranges the VCF must have a Tabix index file. An index file can be created with bzip and indexTabix functions. See examples.

readVcf calls [scanVcf](#), the details of which can be found with `?scanVcf`.

Data type : CHROM, POS, ID and REF fields are used to create the GRanges stored in the rowData slot of the VCF object. Access with rowData accessor.

REF, ALT, QUAL and FILTER are parsed into the DataFrame in the fixed slot. Because ALT can have more than one value per variant it is represented as a DNAStrngSetList. REF is a DNAStrngSet, QUAL is numeric and FILTER is a character. Accessors include fixed, ref, alt, qual, and filt.

Data from the INFO field can be accessed with the info accessor. Genotype data (i.e., data immediately following the FORMAT field in the VCF) can be accessed with the geno accessor. INFO and genotype data types are determined according to the 'Number' and 'Type' information in the file header as follows :

If 'Number' is 1, 'info' data are parsed into a vector. 'geno' data are parsed into a matrix where the columns are the samples.

If 'Number' is an integer >1, 'info' data are parsed into a DataFrame with the indicated number of columns. 'geno' are parsed into an array with the same dimensions as 'Number'. Columns of the 'geno' matrices are the samples.

If 'Number' is '.', 'A' or 'G', a matrix is used for both 'info' and 'geno' data.

When the VCF header does not contain data type information, the data are returned as a single unparsed column named 'INFO' or 'GENO'.

Missing data : Missing data in VCF files are represented by a dot ("."). readVcf retains the dot as a character string for data type character and converts it to NA for data types numeric or double.

Because the data are stored in rectangular data structures there is a value for each info and geno field element in the VCF class. If the element was missing or was not collected for a particular variant the value will be NA.

Value

The object returned is a [VCF](#) class instance. See `?VCF` for complete details of the class structure.

rowData: The CHROM, POS, ID and REF fields are used to create a GRanges object. The ranges are created using POS as the start value and width of the reference allele (REF). The IDs become the rownames. If they are missing (i.e., '.') a colon separated string of chromosome and start position will be used instead. The genome argument is stored in the seqinfo of the GRanges and can be accessed with `genome(<VCF>)`.

One elementMetadata column, paramRangeID, is included with the rowData. This ID is meaningful when multiple ranges are specified in the ScanVcfParam. This ID distinguishes which records match each range.

fixed: REF, ALT, QUAL and FILTER fields of the VCF are parsed into a DataFrame.

info: Data from the INFO field of the VCF is parsed into a DataFrame.

geno: If present, the genotype data are parsed into a list of matrices or arrays. Each list element represents a field in the FORMAT column of the VCF file. Rows are the variants, columns are the samples.

colData: This slot contains a DataFrame describing the samples. If present, the sample names following FORMAT in the VCF file become the row names.

exptData: Header information present in the file is put into a SimpleList in exptData.

See references for complete details of the VCF file format.

## S4 method for signature 'character,character,missing'
readVcfLongForm(file, genome, param, ...)
## S4 method for signature 'character,missing,missing'
readVcfLongForm(file, genome, param, ...)

```

Arguments

file	A TabixFile instance or character() name of the VCF file to be processed. When ranges are specified in param, file must be a TabixFile . Use of the TabixFile methods are encouraged as they are more efficient than the character() methods. See ? TabixFile and ? indexTabix for help creating a TabixFile .
genome	The character() name of the genome the variants are mapped to. This information is stored in the genome slot of the seqinfo associated with the GRanges object in rowData.
param	A instance of ScanVcfParam , GRanges , RangedData or RangesList . VCF files can be subset on genomic coordinates (ranges) or elements in the VCF fields. Both genomic coordinates and VCF elements can be specified in a ScanVcfParam . See ? ScanVcfParam for details.
...	Additional arguments, passed to methods.

Details

Long Form GRanges object : readVcfLongForm reads data from a VCF file in the same manner as readVcf. Input arguments and the ability to subset the data on ranges or VCF fields are the same. The return object is a long form GRanges expanded to the length of the 'unlisted' alternate allele (ALT). The fixed and info data are also expanded as elementMetadata columns. Currently no geno information is included.

Value

A GRanges of variant locations. When the alternate allele column (ALT) column in the VCF file has a single value per variant the GRanges will have a single row per variant (i.e., not expanded). When variants have multiple alternate allele values the GRanges will have repeated rows for the variants with multiple values.

```

```
refLocsToLocalLocs      refLocsToLocalLocs
```

Description

Converts reference locations (aka chromosome-based or genomic) to coding regions, and protein based locations

Usage

```
refLocsToLocalLocs(ranges, txdb, cdsbytx, ...)
## S4 method for signature 'GRanges,TranscriptDb,missing'
refLocsToLocalLocs(ranges, txdb, cdsbytx, ...)
## S4 method for signature 'GRanges,missing,GRangesList'
refLocsToLocalLocs(ranges, txdb, cdsbytx, ...)
```

Arguments

ranges	A GRanges object containing the variants in reference-based coordinates.
txdb	A TranscriptDb object that serves as the annotation reference.
cdsbytx	A GRangesList object with transcripts as the outer list elements and coding regions as the inner.
...	Additional arguments passed to methods

Details

This function translates the reference-based coordinates in ranges to 'local' coordinates in the coding region (CDS) and protein sequences.

When a txdb is supplied the cdsbytx is created with cdsBy(). If cdsbytx is provided the outer list elements must be transcripts and the inner list elements represent coding regions. The GRangesList objects must have names on the outer list elements (i.e., transcript names).

Only ranges that fall 'within' coding sequences are reported in the result. Output is a modified GRanges of the ranges input where each row represents a range-transcript match making multiple rows per range possible. The elementMetadata columns include tx_id, cdsLoc and proteinLoc. When a txdb is provided the txId is the internal transcript id from the annotation. When cdsbytx is provided tx_id are the names on the outer list elements.

If ranges is unstranded the strand of the return value reflects the strand of the subject the ranges overlapped with.

Value

A [GRanges](#) with the following elementMetadata columns,

CDSLLOC Location in coding region coordinates

PROTEINLOC Location in protein (codon triplet) coordinates

QUERYID Character vector mapping to the of rows of the original query

TXID Character vector of internal transcript ids from the [TranscriptDb](#) or the names of the outer list elements of the cdsbytx object.

CDSID Character vector of internal coding region ids from the [TranscriptDb](#) or the names of the outer list elements of the cdsbytx object.

```

Arguments

file	For scanVcf and scanVcfHeader, the character() file name, TabixFile , or class connection (file() or bgzip()) of the 'VCF' file to be processed.
param	A instance of ScanVcfParam influencing which records are parsed and the 'INFO' and 'GENO' information returned.
...	Additional arguments for methods

Details

The argument param allows portions of the file to be input, but requires that the file be bgzip'd and indexed as a [TabixFile](#).

scanVcf with param="missing" and file="character" or file="connection" scan the entire file. With file="connection", an argument n indicates the number of lines of the VCF file to input; a connection open at the beginning of the call is open and incremented by n lines at the end of the call, providing a convenient way to stream through large VCF files.

The INFO field of the scanned VCF file is returned as a single 'packed' vector, as in the VCF file. The GENO field is a list of matrices, each matrix corresponds to a field as defined in the FORMAT field of the VCF header. Each matrix has as many rows as scanned in the VCF file, and as many columns as there are samples. As with the INFO field, the elements of the matrix are 'packed'. The reason that INFO and GENO are returned packed is to facilitate manipulation, e.g., selecting particular rows or samples in a consistent manner across elements.

Value

scanVcfHeader returns a list, with one element for each file named in file. Each element of the

list is itself a list containing three elements. The reference element is a character() vector with names of reference sequences. The sample element is a character() vector of names of samples. The header element is a character() vector of the header lines (preceded by “##”) present in the VCF file.

scanVcf returns a list, with one element per range. Each list has 7 elements, obtained from the columns of the VCF specification:

rowData GRanges instance derived from CHROM, POS, ID, and the width of REF

REF reference allele

ALT alternate allele

QUAL phred-scaled quality score for the assertion made in ALT

FILTER indicator of whether or not the position passed all filters applied

INFO additional information

GENO genotype information immediately following the FORMAT field in the VCF

The GENO element is itself a list, with elements corresponding to those defined in the VCF file header. For scanVcf, elements of GENO are returned as a matrix of records x samples; if the description of the element in the file header indicated multiplicity other than 1 (e.g., variable number for “A”, “G”, or “.”), then each entry in the matrix is a character string with sub-entries comma-delimited.

ScanVcfParam-class *Parameters for scanning VCF files*

Description

Use ScanVcfParam() to create a parameter object influencing which records and fields are imported from a VCF file. Record parsing is based on genomic coordinates and requires a Tabix index file. Individual VCF elements can be specified in the ‘fixed’, ‘info’ and ‘geno’ arguments.

Usage

```
ScanVcfParam(fixed=character(), info=character(), geno=character(),
             trimEmpty=TRUE, which, ...)
```

```
## Getters and Setters
```

```
vcfFixed(object)
vcfFixed(object) <- value
vcfInfo(object)
vcfInfo(object) <- value
vcfGeno(object)
vcfGeno(object) <- value
vcfTrimEmpty(object)
vcfTrimEmpty(object) <- value
vcfWhich(object)
vcfWhich(object) <- value
```

Arguments

fixed	A character() vector of fixed fields to be returned. Possible values are ALT, QUAL and FILTER. The CHROM, POS, ID and REF fields are needed to create the GRanges of variant locations. Because these are essential fields there is no option to request or omit them. If not specified, all fields are returned; if fixed=NA only REF is returned.
info	A character() vector naming the ‘INFO’ fields to return. scanVcfHeader() returns a vector of available fields. If not specified, all fields are returned; if info=NA no fields are returned.
geno	A character() vector naming the ‘GENO’ fields to return. scanVcfHeader() returns a vector of available fields. If not specified, all fields are returned; if geno=NA no fields are returned.
trimEmpty	A logical(1) indicating whether ‘GENO’ fields with no values should be returned.
which	A GRanges or RangedData describing the sequences and ranges to be queried. Variants whose POS lies in the interval(s) [start, end] are returned. If which is not specified all ranges are returned.

object	An instance of class ScanVcfParam.
value	An instance of the corresponding slot, to be assigned to object.
...	Arguments passed to methods.

Objects from the Class

Objects can be created by calls of the form `ScanVcfParam()`.

Slots

which: Object of class "RangesList" indicating which reference sequence and coordinate variants must overlap.

fixed: Object of class "character" indicating fixed fields to be returned.

info: Object of class "character" indicating portions of 'INFO' to be returned.

geno: Object of class "character" indicating portions of 'GENO' to be returned.

trimEmpty: Object of class "logical" indicating whether empty 'GENO' fields are to be returned.

Functions and methods

See 'Usage' for details on invocation.

Constructor:

ScanVcfParam: Returns a ScanVcfParam object. The which argument to the constructor can be one of several types, as documented above.

Accessors:

vcfFixed, vcfInfo, vcfGeno, vcfTrimEmpty, vcfWhich: Return the corresponding field from object.

Methods:

show Compactly display the object.

grl <- GRangesList("1"=gr1, "2"=gr2)
vcf <- readVcf(tab, "hg19", grl)

## Names of the individual ranges are returned in the
## 'paramRangeID' column in the rowData,
rowData(vcf)

## which can be used for subsetting the VCF object
vcf[rowData(vcf)$paramRangeID == "regionA"]

## When using ranges, the seqnames must correspond to valid
## chromosome names in the vcf file.
gr <- unlist(grl, use.names=FALSE)
vcf <- readVcf(tab, "hg19", gr)

## -----
## 'fixed', 'info' and 'geno' arguments
## -----
## This param specifies the "GT" 'geno' field and the
## subset of ranges in 'which'. All 'fixed' and 'info' fields will be
## returned.
ScanVcfParam(geno="GT", which=gr)

## Here two 'fixed' and one 'geno' field are specified
ScanVcfParam(fixed=c("ALT", "QUAL"), geno="GT", info=NA)

## Return only the 'fixed' fields
ScanVcfParam(geno=NA, info=NA)

```

SIFTDb-class

SIFTDb objects

Description

The SIFTDb class is a container for storing a connection to a SIFT sqlite database.

Details

SIFT is a sequence homology-based tool that sorts intolerant from tolerant amino acid substitutions and predicts whether an amino acid substitution in a protein will have a phenotypic effect. SIFT is based on the premise that protein evolution is correlated with protein function. Positions important for function should be conserved in an alignment of the protein family, whereas unimportant positions should appear diverse in an alignment.

SIFT uses multiple alignment information to predict tolerated and deleterious substitutions for every position of the query sequence. The procedure can be outlined in the following steps,

- search for similar sequences
- choose closely related sequences that may share similar function to the query sequence
- obtain the alignment of the chosen sequences
- calculate normalized probabilities for all possible substitutions from the alignment.

Positions with normalized probabilities less than 0.05 are predicted to be deleterious, those greater than or equal to 0.05 are predicted to be tolerated.

Methods

In the code below, `x` is a SIFTDb object.

`metadata(x)`: Returns `x`'s metadata in a data frame.

`cols(x)`: Returns the names of the `cols` that can be used to subset the data columns.

`keys(x)`: Returns the names of the keys that can be used to subset the data rows. The keys values are the `rsid`'s.

`select(x, keys = NULL, cols = NULL, ...)`: Returns a subset of data defined by the character vectors `keys` and `cols`. If no keys are supplied, all rows are returned. If no `cols` are supplied, all columns are returned. For column descriptions see `?SIFTDbColumns`.

SIFTdbColumns

SIFTdb Columns

Description

Description of the SIFT Sqlite Database Columns

Column descriptions

These column names are displayed when `cols` is called on a SIFTdb object.

- **RSID** : rsid
- **PROTEINID** : NCBI RefSeq protein ID
- **AACHANGE** : amino acid substitution; reference aa is preceeding, followed by the position and finally the snp aa
- **METHOD** : method of obtaining related sequences using PSI-BLAST
- **AA** : either the reference or snp residue amino acid
- **PREDICTION** : SIFT prediction
- **SCORE** : SIFT score (range 0 to 1)
 - **TOLERATED** : score is greater than 0.05
 - **DAMAGING** : score is less than or equal to 0.05
 - **NOT SCORED** : no prediction is made if there are less than 2 homologous sequences that have an amino acid at the position of the given SNP or if the SIFT prediction is not available
- **MEDIAN** : diversity measurement of the sequences used for prediction (range 0 to 4.32)
- **POSITIONSEQS** : number of sequences with an amino acide at the position of prediction
- **TOTALSEQS** : total number of sequences in alignment

snpSummary

Counts and distribution statistics for SNPs in a VCF object

Description

Counts and distribution statistics for SNPs in a VCF object

Usage

```
## S4 method for signature 'CollapsedVCF'  
snpSummary(x, ...)
```

Arguments

x A [CollapsedVCF](#) object.
... Additional arguments to methods.

Details

Genotype counts, allele counts and Hardy Weinberg equilibrium (HWE) statistics are calculated for single nucleotide variants in a [CollapsedVCF](#) object. HWE has been established as a useful quality filter on genotype data. This equilibrium should be attained in a single generation of random mating. Departures from HWE are indicated by small p values and are almost invariably indicative of a problem with genotype calls.

The following caveats apply:

- No distinction is made between phased and unphased genotypes.
- Only diploid calls are included.
- Only 'valid' SNPs are included. A 'valid' SNP is defined as having a reference allele of length 1 and a single alternate allele of length 1.

Variants that do not meet these criteria are set to NA.

Value

The object returned is a `data.frame` with seven columns.

g00 Counts for genotype 00 (homozygous reference).

g01 Counts for genotype 01 or 10 (heterozygous).

g11 Counts for genotype 11 (homozygous alternate).

a0Freq Frequency of the reference allele.

a1Freq Frequency of the alternate allele.

HWEzscore Z-score for departure from a null hypothesis of Hardy Weinberg equilibrium.

HWEpvalue p-value for departure from a null hypothesis of Hardy Weinberg equilibrium.

[genotypeToSnpMatrix](#), [probabilityToSnpMatrix](#)

Examples

```
f1 <- system.file("extdata", "ex2.vcf", package="VariantAnnotation")
vcf <- readVcf(f1, "hg19")

## The return value is a data.frame with genotype counts
## and allele frequencies.
df <- snpSummary(vcf)
df

## Compare to ranges in the VCF object:
rowData(vcf)

## No statistics were computed for the variants in rows 3, 4
## and 5. They were omitted because row 3 has two alternate
## alleles, row 4 has none and row 5 is not a SNP.
```

summarizeVariants *Summarize variants by sample*

Description

Variants in a VCF file are overlapped with an annotation region and summarized by sample. Genotype information in the VCF is used to determine which samples express each variant.

Usage

```

## S4 method for signature 'TranscriptDb,VCF,CodingVariants'
summarizeVariants(query, subject, mode, ...)
## S4 method for signature 'TranscriptDb,VCF,FiveUTRVariants'
summarizeVariants(query, subject, mode, ...)
## S4 method for signature 'TranscriptDb,VCF,ThreeUTRVariants'
summarizeVariants(query, subject, mode, ...)
## S4 method for signature 'TranscriptDb,VCF,SpliceSiteVariants'
summarizeVariants(query, subject, mode, ...)
## S4 method for signature 'TranscriptDb,VCF,IntronVariants'
summarizeVariants(query, subject, mode, ...)
## S4 method for signature 'TranscriptDb,VCF,PromoterVariants'
summarizeVariants(query, subject, mode, ...)
## S4 method for signature 'GRangesList,VCF,VariantType'
summarizeVariants(query, subject, mode, ...)
## S4 method for signature 'GRangesList,VCF,function'
summarizeVariants(query, subject, mode, ...)

```

Arguments

query	A TranscriptDb or GRangesList object that serves as the annotation. GFF files can be converted to TranscriptDb objects with <code>makeTranscriptDbFromGFF()</code> in the <code>GenomicFeatures</code> package.
subject	A VCF object containing the variants.
mode	mode can be a VariantType class or the name of a function. When mode is a VariantType class, counting is done with <code>locateVariants</code> and counts are summarized transcript-by-sample. Supported VariantType classes include <code>CodingVariants</code> , <code>IntronVariants</code> , <code>FiveUTRVariants</code> , <code>ThreeUTRVariants</code> , <code>SpliceSiteVariants</code> or <code>PromoterVariants</code> . <code>AllVariants()</code> and <code>IntergenicVariants</code> are not supported. See <code>?locateVariants</code> for more detail on the variant classes. mode can also be the name of any counting function that outputs a <code>Hits</code> object. Variants will be summarized by the length of the GRangesList annotation (i.e., 'length-of- GRangesList '-by-sample).
...	Additional arguments passed to methods such as ignore.strand A logical indicating if strand should be ignored when performing overlaps.

Details

`summarizeVariants` uses the genotype information in a VCF file to determine which samples are positive for each variant. Variants are overlapped with the annotation and the counts are summarized annotation-by-sample. If the annotation is a [GRangesList](#) of transcripts, the count matrix will be transcripts-by-sample. If the [GRangesList](#) is genes, the count matrix will be gene-by-sample.

- Counting with `locateVariants()` :
Variant counts are always summarized transcript-by-sample. When query is a [GRangesList](#), it must be compatible with the [VariantType](#)-class given as the mode argument. The list below specifies the appropriate [GRangesList](#) for each mode.

CodingVariants : coding (CDS) by transcript

IntronVariants : introns by transcript

FiveUTRVariants : five prime UTR by transcript

ThreeUTRVariants : three prime UTR by transcript

SpliceSiteVariants : introns by transcript

PromoterVariants : list of transcripts

When query is a TranscriptDb, the appropriate region-by-transcript GRangesList listed above is extracted internally and used as the annotation.

- Counting with a user-supplied function :
subject must be a GRangesList and mode must be the name of a function. The count function must take 'query' and 'subject' arguments and return a Hits object. Counts are summarized by the outer list elements of the GRangesList.

Value

A SummarizedExperiment object with count summaries in the assays slot. The rowData contains the annotation used for counting. Information in colData and exptData are taken from the VCF file.

VariantType-class	<i>VariantType subclasses</i>
-------------------	-------------------------------

Description

VariantType subclasses specify the type of variant to be located with locateVariants.

Usage

```

CodingVariants()
IntronVariants()
FiveUTRVariants()
ThreeUTRVariants()
SpliceSiteVariants()
IntergenicVariants()
PromoterVariants(upstream = 2000, downstream = 200)
AllVariants(upstream = 2000, downstream = 200)

```

Arguments

upstream	A numeric indicating the number of base pairs upstream of the 5'-end.
downstream	A numeric indicating the number of base pairs downstream of the 3'-end.

Details

VariantType is a virtual class inherited by the CodingVariants, IntronVariants, FiveUTRVariants, ThreeUTRVariants, SpliceSiteVariants, IntergenicVariants and AllVariants subclasses.

The subclasses are used as the region argument to locateVariants. They designate the type of variant (i.e., region of the annotation to match) when calling locateVariants.

The majority of subclasses have no slots and require no arguments for an instance to be created. The two exceptions are `PromoterVariants` and `AllVariants`. These classes have slots for the number of base pairs upstream of the 5'-end and downstream of the 3'-end of the transcript region.

Accessors

In the following code, `x` is a `PromoterVariants` or a `AllVariants` object.

`upstream(x)`, `upstream(x) <- value`: Gets or sets the number of base pairs defining a range upstream of the 5' end (excludes 5' start value).

`downstream(x)`, `downstream(x) <- value`: Gets or sets the number of base pairs defining a range downstream of the 3' end (excludes 3' end value).

Author(s)

Valerie Obenchain <vobencha@fhcrc.org>

Examples

```
CodingVariants()
SpliceSiteVariants()
PromoterVariants(upstream=1000, downstream=10000)
```

VCF-class

VCF class objects

Description

The VCF class is a virtual class extended from `SummarizedExperiment`. The subclasses, `CompressedVCF` and `ExtendedVCF`, are containers for holding data from Variant Call Format files.

Details

The VCF class is a virtual class with two concrete subclasses, `CollapsedVCF` and `ExtendedVCF`.

Slots unique to VCF and subclasses,

- `fixed`: A `DataFrame` containing information from the REF, ALT, QUAL and FILTER fields from a VCF file.
- `info`: A `DataFrame` containing information from the INFO fields from a VCF file.

Slots inherited from `SummarizedExperiment`,

- `exptData`: A `SimpleList`-class instance containing the file header or other information about the overall experiment.
- `rowData`: A `GRanges`-class instance defining the variant ranges and associated metadata columns of REF, ALT, QUAL and FILTER.
- `colData`: A `DataFrame`-class instance describing the samples and associated metadata.

- `geno`: The assays slot from `SummarizedExperiment` has been renamed as `geno` for the `VCF` class. This slot contains the genotype information immediately following the `FORMAT` field in a VCF file. Each element of the `list` or `SimpleList` is a matrix or array.

It is expected that users will not create instances of the `VCF` class but instead one of the concrete sub-classes, `CollapsedVCF` or `ExpandedVCF`. `CollapsedVCF` contains the ALT data as a `DNAStrngSetList` allowing for multiple alleles per variant. The `ExpandedVCF` ALT data is a `DNAStrngSet` where the ALT column has been expanded to create a flat form of the data with one row per variant-allele combination. In the case of structural variants, ALT will be a `CompressedCharacterList` or character in the collapsed or expanded forms.

Constructors

`readVcf(rowData = GRanges(), colData = DataFrame(), exptData = SimpleList(), fixed = DataFrame())`
Creates a `CollapsedVCF` class from data in a Variant Call Format file on disk.

`expand(rowData = GRanges(), colData = DataFrame(), exptData = SimpleList(), fixed = DataFrame())`
Creates an `ExpandedVCF` from a `CollapsedVCF`.

`VCF(rowData = GRanges(), colData = DataFrame(), exptData = SimpleList(header = VCFHeader()))`
Low-level constructor. Generally not used directly. If `collapsed = TRUE` a `CollapsedVCF` is created, else an `ExpandedVCF`.

Accessors

In the following code snippets `x` is a `CollapsedVCF` or `ExpandedVCF` object.

`rowData(x), rowData(x) <- value`: Gets or sets a `GRanges` constructed from the `CHROM`, `POS` and `ID` fields of the VCF file with `REF`, `ALT`, `QUAL` and `FILT` as metadata columns. The `ID`'s serve as the rownames; if they are `NULL`, rownames are constructed from `CHROM:POS`. `value` must be a `GRanges` with metadata columns.

The `paramRangeID` metadata column groups ranges as specified with `ScanVcfParam`. If `ScanVcfParam` was not used with `readVcf` these values will be `NA`.

The metadata columns can be accessed with `mcols(x)$<variable>` or the following accessors:

- `ref(x), ref(x) <- value`: Gets or sets the reference allele (`REF`). `value` must be a `DNAStrngSet`.
- `alt(x), alt(x) <- value`: Gets or sets the alternate allele data (`ALT`). When `x` is a `CollapsedVCF`, `value` must be a `DNAStrngSetList` or `CompressedCharacterList`. For `ExpandedVCF`, `value` must be a `DNAStrngSet` or character.
- `qual(x), qual(x) <- value`: Returns or sets the quality scores (`QUAL`). `value` must be an `integer(1L)`.
- `filt(x), filt(x) <- value`: Returns or sets the filter data (`FILT`). `value` must be a `character(1L)`.

`info(x), info(x) <- value`: Gets or sets a `DataFrame` of `INFO` variables.

`geno(x), geno(x) <- value`: Gets a `SimpleList` of genotype data. `value` is a `SimpleList`. To replace a single variable in the `SimpleList` use `geno(x)$variable <- value`; in this case `value` must be a matrix or array.

`exptData(x)`: Gets a SimpleList of experiment-related data. By default this list includes the ‘header’ information from the VCF file. See the use of `header()` for details in extracting header information.

`colData(x), colData(x) <- value`: Gets or sets a DataFrame of sample-specific information. Each row represents a sample in the VCF file. `value` must be a DataFrame with rownames representing the samples in the VCF file.

`genome(x)`: Extract the genome information from the GRanges in the rowData slot.

`seqlevels(x)`: Extract the seqlevels from the GRanges in the rowData slot.

`strand(x)`: Extract the strand from the GRanges in the rowData slot.

`header(x)`: Extract the VCF header information.

- `info(header(x))`
- `geno(header(x))`
- `meta(header(x))`
- `samples(header(x))`

Subsetting and combining

In the following code `x` is a VCF object, and `...` is a list of VCF objects.

`x[i, j], x[i, j] <- value`: Gets or sets rows and columns. `i` and `j` can be integer or logical vectors. `value` is a replacement VCF object.

`cbind(...), rbind(...)`: `cbind` combines objects with identical ranges (`rowData`) but different samples (columns in assays). The colnames in `colData` must match or an error is thrown. Columns with duplicate names in `fixed`, `info` and `mcols(rowData(VCF))` must contain the same data.

`rbind` combines objects with different ranges (`rowData`) and the same subjects (columns in assays). Columns with duplicate names in `colData` must contain the same data. The ‘Samples’ columns in `colData` (created by `readVcf`) are renamed with a numeric extension ordered as they were input to `rbind` e.g., “Samples.1, Samples.2, ...” etc.

`exptData` from all objects are combined into a SimpleList with no name checking.

TODO: header information not yet combined

Other methods

In the following code snippets `x` is a VCF object.

`renameSeqlevels(x, value)`: Rename the seqlevels in the GRanges in the rowData slot of the VCF object. `value` is a named character vector where the names are the old seqlevels and the values are the new.

`keepSeqlevels(x, value)`: Subset the GRanges in the rowData slot of the VCF object. `value` is a character vector of seqlevels to keep.

expand

In the following code snippets `x` is a CollapsedVCF object.

`expand(x)`: Expand (unlist) the ALT column of a `CollapsedVCF` object to one row per ALT value. In addition to ALT, all variables with `Number='A'` in the header are also expanded. The 'A' indicates one value per alternate allele. Data without `Number='A'` in the header are replicated the appropriate number of times.

The output is an `ExpandedVCF` object with ALT as a `DNAStrngSet` or character (structural variants).

Arguments

- geno** A list or `SimpleList` of matrix elements, or a matrix containing the genotype information from a VCF file. If present, these data immediately follow the `FORMAT` field in the VCF. Each element of the list must have the same dimensions, and dimension names (if present) must be consistent across elements and with the row names of `rowData`, `colData`.
- info** A `DataFrame` of data from the `INFO` field of a VCF file. The number of rows must match that in the `rowData` object.
- fixed** A `DataFrame` of `REF`, `ALT`, `QUAL` and `FILTER` fields from a VCF file. The number of rows must match that of the `rowData` object.
- rowData** A `GRanges` instance describing the ranges of interest. Row names, if present, become the row names of the VCF. The length of the `GRanges` must equal the number of rows of the matrices in `geno`.
- colData** A `DataFrame` describing the samples. Row names, if present, become the column names of the VCF.
- exptData** A `SimpleList` describing the header of the VCF file or additional information for the overall experiment.
- ...** For `cbind` and `rbind` a list of VCF objects. For all other methods ... are additional arguments passed to methods.
- collapsed** A `logical(1)` indicating whether a `CollapsedVCF` or `ExpandedVCF` should be created. The ALT in a `CollapsedVCF` is a `DNAStrngSetList` while in a `ExpandedVCF` it is a `DNAStrngSet`.
- verbose** A `logical(1)` indicating whether messages about data coercion during construction should be printed.

## -----
## readVCF() produces a CollapsedVCF object.
fl <- system.file("extdata", "ex2.vcf",
                  package="VariantAnnotation")
vcf <- readVcf(fl, genome="hg19")
vcf

## The ALT column is a DNASTringSetList to allow for more
## than one alternate allele per variant.
alt(vcf)

## When structural variants are present, ALT is
## a CompressedCharacterList.
fl <- system.file("extdata", "structural.vcf",
                  package="VariantAnnotation")

```

```
vcf <- readVcf(fl, genome="hg19")
alt(vcf)

## -----
## ExpandedVCF
## -----
## ExpandedVCF is the 'flattened' counterpart of CollapsedVCF.
## The ALT and all variables with Number='A' in the header are
## expanded to one row per alternate allele.
fl <- system.file("extdata", "ex2.vcf", package="VariantAnnotation")
vcf <- readVcf(fl, genome="hg19")
vcfLong <- expand(vcf)
alt(vcfLong)
```

VCFHeader-class	<i>VCFHeader instances</i>
-----------------	----------------------------

Description

The VCFHeader class holds Variant Call Format (VCF) file header information and is produced from a call to `scanVcfHeader`.

Details

The VCFHeader class holds header information from a VCF file.

Slots :

reference character() vector

sample character() vector

header [DataFrameList-class](#)

Constructor

```
VCFHeader(reference = character(), samples = character(), header = DataFrameList(), ...)
```

Accessors

In the following code snippets `x` is a VCFHeader object.

`samples(x)`: Returns a character() vector of names of samples.

`header(x)`: Returns all information in the header slot which includes meta, info and geno if present.

`meta(x)`: Returns a DataFrameList of meta information. This includes any information represented as simple key=value pairs in the VCF file header.

`fixed(x)`: Returns a DataFrameList of information pertaining to any of 'REF', 'ALT', 'FILTER' and 'QUAL'.

info(x): Returns a DataFrame of 'INFO' information.

geno(x): Returns a DataFrame of 'FORMAT' information.

reference(x): Returns a character() vector with names of reference sequences. Not relevant for scanVcfHeader.

Arguments

reference A character() vector of sequences.

sample A character() vector of sample names.

header A DataFrameList of parsed header lines (preceded by "##") present in the VCF file.

... Additional arguments passed to methods.

Author(s)

Valerie Obenchain <vobencha@fhcrc.org>

See Also

[scanVcfHeader](#), [DataFrameList](#)

Examples

```
f1 <- system.file("extdata", "structural.vcf", package="VariantAnnotation")
hdr <- scanVcfHeader(f1)

fixed(hdr)
info(hdr)
geno(hdr)
```

writeVcf

Write VCF files

Description

Write Variant Call Format (VCF) files to disk

Usage

```
## S4 method for signature 'VCF,character'
writeVcf(obj, filename, index = FALSE, ...)
## S4 method for signature 'VCF,connection'
writeVcf(obj, filename, index = FALSE, ...)
```

Arguments

obj	Object containing data to be written out. At present only accepts VCF .
filename	The character() name of the VCF file, or a connection (e.g., file()), to be written out. A connection opened with open = "a" will have header information written only if the file does not already exist.
index	Whether to bgzip the output file and generate a tabix index.
...	Additional arguments, passed to methods.

Details

A VCF file can be written out from data in a VCF file. More general methods to write out from other objects may be added in the future.

Value

VCF file

Author(s)

Valerie Obenchain <vobencha@fhcrc.org> and Michael Lawrence

References

<http://vcftools.sourceforge.net/specs.html> outlines the VCF specification.

[readVcf](#)

Examples

```
f1 <- system.file("extdata", "ex2.vcf", package="VariantAnnotation")

out1.vcf <- tempfile()
out2.vcf <- tempfile()
in1 <- readVcf(f1, "hg19")
writeVcf(in1, out1.vcf)
in2 <- readVcf(out1.vcf, "hg19")
writeVcf(in2, out2.vcf)
in3 <- readVcf(out2.vcf, "hg19")
stopifnot(all(in2 == in3))

## write to console
writeVcf(in1, stdout())

## write incrementally
```

```
out3.vcf <- tempfile()
con <- file(out3.vcf, open="a")
writeVcf(in1[1:2,], con)
writeVcf(in1[-(1:2),], con)
close(con)
readVcf(out3.vcf, "hg19")
```
