# 1 Overview of GEO

The NCBI Gene Expression Omnibus (GEO) serves as a public repository for a wide range of high-throughput experimental data. These data include single and dual channel microarray-based experiments measuring mRNA, genomic DNA, and protein abundance, as well as non-array techniques such as serial analysis of gene expression (SAGE), mass spectrometry proteomic data, and high-throughput sequencing data.

At the most basic level of organization of GEO, there are four basic entity types. The first three (Sample, Platform, and Series) are supplied by users; the fourth, the dataset, is compiled and curated by GEO staff from the user-submitted data.<sup>1</sup>

## 1.1 Platforms

A Platform record describes the list of elements on the array (e.g., cDNAs, oligonucleotide probesets, ORFs, antibodies) or the list of elements that may be detected and quantified in that experiment (e.g., SAGE tags, peptides). Each Platform record is assigned a unique and stable GEO accession number (GPLxxx). A Platform may reference many Samples that have been submitted by multiple submitters.

## 1.2 Samples

A Sample record describes the conditions under which an individual Sample was handled, the manipulations it underwent, and the abundance measurement of each element derived from it. Each Sample record is assigned a unique and stable GEO accession number (GSMxxx). A Sample entity must reference only one Platform and may be included in multiple Series.

## 1.3 Series

A Series record defines a set of related Samples considered to be part of a group, how the Samples are related, and if and how they are ordered. A Series provides a focal point and description of the experiment as a whole. Series records may also contain tables describing extracted data, summary conclusions, or analyses. Each Series record is assigned a unique and stable GEO accession number (GSExxx). Series records are available in a couple of formats which are handled by GEOquery independently. The smaller and new GSEMatrix files are quite fast to parse; a simple flag is used by GEOquery to choose to use GSEMatrix files (see below).

## 1.4 Datasets

GEO DataSets (GDSxxx) are curated sets of GEO Sample data. A GDS record represents a collection of biologically and statistically comparable GEO Samples and forms the basis

---

<sup>1</sup>See <http://www.ncbi.nih.gov/geo> for more information

of GEO's suite of data display and analysis tools. Samples within a GDS refer to the same Platform, that is, they share a common set of probe elements. Value measurements for each Sample within a GDS are assumed to be calculated in an equivalent manner, that is, considerations such as background processing and normalization are consistent across the dataset. Information reflecting experimental design is provided through GDS subsets.

## 2 Getting Started using GEOquery

Getting data from GEO is really quite easy. There is only one command that is needed, `getGEO`. This one function interprets its input to determine how to get the data from GEO and then parse the data into useful R data structures. Usage is quite simple:

```
> library(GEOquery)
```

This loads the GEOquery library.

```
> gds <- getGEO("GDS12")
```

```
File stored at:  
/tmp/Rtmpebe30h/GDS12.soft
```

Now, `gds` contains the R data structure (of class *GDS*) that represents the GDS1 entry from GEO. You'll note that the filename used to store the download was output to the screen (but not saved anywhere) for later use to a call to `getGEO(filename=...)`.

We can do the same with any other GEO accession, such as GSM3, a GEO sample.

```
> gsm <- getGEO("GSM3")
```

```
File stored at:  
/tmp/Rtmpebe30h/GSM3.soft
```

## 3 GEOquery Data Structures

The GEOquery data structures really come in two forms. The first, comprising *GDS*, *GPL*, and *GSM* all behave similarly and accessors have similar effects on each. The fourth GEOquery data structure, *GSE* is a composite data type made up of a combination of *GSM* and *GPL* objects. I will explain the first three together first.

### 3.1 The GDS, GSM, and GPL classes

Each of these classes is comprised of a metadata header (taken nearly verbatim from the SOFT format header) and a GEODataTable. The GEODataTable has two simple parts, a Columns part which describes the column headers on the Table part. There is also a *show* method for each class. For example, using the gsm from above:

```

### 3.2 The GSE class

The *GSE* is the most confusing of the GEO entities. A GSE entry can represent an arbitrary number of samples run on an arbitrary number of platforms. The *GSE* has a metadata section, just like the other classes. However, it doesn't have a `GEODataTable`. Instead, it contains two lists, accessible using `GPLList` and `GSMList`, that are each lists of *GPL* and *GSM* objects. To show an example:

```
> gse <- getGEO("GSE462", GSEMatrix = FALSE)
```

```
File stored at:
```

```
/tmp/Rtmpebe30h/GSE462.soft
```

```

## 4 Converting to BioConductor ExpressionSets and limma MALists

GEO datasets are (unlike some of the other GEO entities), quite similar to the *limma* data structure *MAList* and to the *Biobase* data structure *ExpressionSet*. Therefore, there are two functions, `GDS2MA` and `GDS2eSet` that accomplish that task.

### 4.1 Getting GSE Series Matrix files as an ExpressionSet

GEO Series are collections of related experiments. In addition to being available as SOFT format files, which are quite large, NCBI GEO has prepared a simpler format file based on tab-delimited text. The `getGEO` function can handle this format and will parse very large GSEs quite quickly. The data structure returned from this parsing is a list of *ExpressionSets*. As an example, we download and parse GSE2553.

```
> gse2553 <- getGEO("GSE2553", GSEMatrix = TRUE)
```

```
Found 1 file(s)
```

```
GSE2553_series_matrix.txt.gz
```

```
File stored at:
```

```
/tmp/Rtmpebe30h/GPL1977.soft
```

```
> show(gse2553)
```

```

$GSE2553_series_matrix.txt.gz
ExpressionSet (storageMode: lockedEnvironment)
assayData: 12600 features, 181 samples
  element names: exprs
phenoData
  sampleNames: GSM48681, GSM48682, ..., GSM48861 (181 total)
  varLabels and varMetadata description:

    PenAt: NA
    ...: ...
    Chimeric_Cluster_IDs: NA
    (13 total)
  additional fvarMetadata: Column, Description
experimentData: use 'experimentData(object)'
Annotation: GPL1977

```

```
> show(pData(phenoData(gse2553[[1]]))[1:5, c(1, 6, 8)])
```

		title	type
GSM48681	Patient sample ST18,	Dermatofibrosarcoma	RNA
GSM48682	Patient sample ST410,	Ewing Sarcoma	RNA
GSM48683	Patient sample ST130,	Sarcoma, NOS	RNA
GSM48684	Patient sample ST293,	Malignant Peripheral Nerve Sheath Tumor	RNA
GSM48685	Patient sample ST367,	Liposarcoma	RNA
	source_name_ch1		
GSM48681	Dermatofibrosarcoma		
GSM48682	Ewing Sarcoma		
GSM48683	Sarcoma, NOS		
GSM48684	Malignant Peripheral Nerve Sheath Tumor		
GSM48685	Liposarcoma		

## 4.2 Converting GDS to an ExpressionSet

Taking our `gds` object from above, we can simply do:

```
> eset <- GDS2eSet(gds, do.log2 = TRUE)
```

File stored at:  
/tmp/Rtmpebe30h/GPL44.annot

Now, `eset` is an *ExpressionSet* that contains the same information as in the GEO dataset, including the sample information, which we can see here:

```
> eset
```

```
ExpressionSet (storageMode: lockedEnvironment)
assayData: 17588 features, 8 samples
  element names: exprs
phenoData
  sampleNames: GSM834, GSM835, ..., GSM841 (8 total)
  varLabels and varMetadata description:
    sample: NA

GSM837 Value for GSM837: HS-5_04; src: HS-5 RNA; src: Universal human reference RNA
GSM838 Value for GSM838: HS-27a_31; src: HS-27a RNA; src: Universal human reference RNA
GSM839 Value for GSM839: HS-27a_27; src: HS-27a RNA; src: Universal human reference RNA
GSM840 Value for GSM840: HS-27a_09; src: HS-27a RNA; src: Universal human reference RNA
GSM841 Value for GSM841: HS-27a_05; src: HS-27a RNA; src: Universal human reference RNA
```

### 4.3 Converting GDS to an MAList

No annotation information (called platform information by GEO) was retrieved from because *ExpressionSet* does not contain slots for gene information, typically. However, it is easy to obtain this information. First, we need to know what platform this GDS used. Then, another call to `getGEO` will get us what we need.

```
> Meta(gds)$platform
```

```
[1] "GPL44"
```

```
> gpl <- getGEO("GPL5")
```

```
File stored at:
```

```
/tmp/Rtmpebe30h/GPL5.soft
```

So, `gpl` now contains the information for GPL5 from GEO. Unlike *ExpressionSet*, the limma *MAList* does store gene annotation information, so we can use our newly created `gpl` of class *GPL* in a call to `GDS2MA` like so:

```
> MA <- GDS2MA(gds, GPL = gpl)
```

```
> MA
```

```
An object of class "MAList"
```

```
$M
```

```

Now, `MA` is of class *MAList* and contains not only the data, but the sample information and gene information associated with GDS1.

## 4.4 Converting GSE to an ExpressionSet

First, make sure that using the method described above in the section “Getting GSE Series Matrix files as an ExpressionSet” for using GSE Series Matrix files is not sufficient for the task, as it is much faster and simpler. If it is not (i.e., other columns from each GSM are needed), then this method will be needed.

Converting a *GSE* object to an *ExpressionSet* object currently takes a bit of R data manipulation due to the varied data that can be stored in a *GSE* and the underlying *GSM* and *GPL* objects. However, using a simple example will hopefully be illustrative of the technique.

First, we need to make sure that all of the *GSMs* are from the same platform:

```
> gsmplatforms <- lapply(GSMList(gse), function(x) {  
+   Meta(x)$platform  
+ })  
> gsmplatforms
```

```
$GSM10  
[1] "GPL5"
```

```
$GSM3  
[1] "GPL5"
```

```
$GSM4  
[1] "GPL5"
```

```
$GSM5  
[1] "GPL5"
```

```
$GSM6  
[1] "GPL5"
```

```
$GSM7
[1] "GPL5"
```

```
$GSM8
[1] "GPL5"
```

```
$GSM9
[1] "GPL5"
```

Indeed, they all used GPL5 as their platform (which we could have determined by looking at the GPLList for `gse`, which shows only one GPL for this particular GSE.). So, now we would like to know what column represents the data that we would like to extract. Looking at the first few rows of the Table of a single GSM will likely give us an idea (and by the way, GEO uses a convention that the column that contains the single “measurement” for each array is called the “VALUE” column, which we could use if we don’t know what other column is most relevant).

```
> Table(GSMList(gse)[[1]])[1:5, ]
```

	ID_REF	SIGNAL_RAW	BKD_FORM	NORM_FORM	BKD_RAW	NORM_VALUE	CONST	VALUE
1	1	4486.49	0	0	3379.579	23337.54	39542	55845.45
2	2	3482.51	0	0	3379.579	23337.54	39542	41058.05
3	3	3812.39	0	0	3379.579	23337.54	39542	45916.78
4	4	3257.56	1	0	3379.579	23337.54	39542	37744.81
5	5	5436.91	0	0	3379.579	23337.54	39542	69843.97

```
> Columns(GSMList(gse)[[1]])[1:5, ]
```

	Column	Description
1	ID_REF	
2	SIGNAL_RAW	raw signal
3	BKD_FORM	
4	NORM_FORM	
5	BKD_RAW	raw background

We will indeed use the “VALUE” column. We then want to make a matrix of these values like so:

```
> probesets <- Table(GPLList(gse)[[1]])$ID
> data.matrix <- do.call("cbind", lapply(GSMList(gse), function(x) {
+   tab <- Table(x)
+   mymatch <- match(probesets, tab$ID_REF)
+   return(tab$VALUE[mymatch])
+ })))
```

```

> data.matrix <- apply(data.matrix, 2, function(x) {
+   as.numeric(as.character(x))
+ })
> data.matrix <- log2(data.matrix)
> data.matrix[1:5, ]
      GSM10   GSM3   GSM4   GSM5   GSM6   GSM7   GSM8   GSM9
[1,] 15.76915 16.22921 16.13000 15.65034 17.09214 15.45853 16.09474 15.23515
[2,] 15.32538 15.26597      NaN 15.20406 16.47596 14.85776 15.14885 14.89007
[3,] 15.48673 15.80932 14.16259 15.18048 16.21235 15.06094 15.38242 14.96986
[4,] 15.20399 15.50663 13.41582 15.05939 16.18593 14.79861 14.80460 15.01923
[5,] 16.09185 17.82246 18.38270 16.24570 16.60964 15.90011 16.00962 15.88859

```

Note that we do a “match” to make sure that the values and the platform information are in the same order. Finally, to make the *ExpressionSet* object:

```

> require(Biobase)
> rownames(data.matrix) <- probesets
> colnames(data.matrix) <- names(GSMList(gse))
> pdata <- data.frame(samples = names(GSMList(gse)))
> rownames(pdata) <- names(GSMList(gse))
> pheno <- as(pdata, "AnnotatedDataFrame")
> eset2 <- new("ExpressionSet", exprs = data.matrix, phenoData = pheno)
> eset2

```

```

ExpressionSet (storageMode: lockedEnvironment)
assayData: 3455 features, 8 samples
  element names: exprs
phenoData
  sampleNames: GSM10, GSM3, ..., GSM9 (8 total)
  varLabels and varMetadata description:
    samples: NA
featureData
  featureNames: 1, 2, ..., 3455 (3455 total)
  fvarLabels and fvarMetadata description: none
experimentData: use 'experimentData(object)'
Annotation:

```

So, using a combination of `lapply` on the `GSMList`, one can extract as many columns of interest as necessary to build the data structure of choice. Because the GSM data from the GEO website are fully downloaded and included in the *GSE* object, one can extract foreground and background as well as quality for two-channel arrays, for example. Getting array annotation is also a bit more complicated, but by replacing “platform” in the `lapply` call to get platform information for each array, one can get other information associated with each array. Future work with this package will likely focus on better tools for manipulating *GSE* data.

## 5 Accessing Raw Data from GEO

NCBI GEO accepts (but has not always required) raw data such as .CEL files, .CDF files, images, etc. Sometimes, it is useful to get quick access to such data. A single function, `getGEOSuppFiles`, can take as an argument a GEO accession and will download all the raw data associate with that accession. By default, the function will create a directory in the current working directory to store the raw data for the chosen GEO accession. Combining a simple `sapply` statement or other loop structure with `getGEOSuppFiles` makes for a very simple way to get gobs of raw data quickly and easily without needing to know the specifics of GEO raw data URLs.

## 6 Conclusion

The GEOquery package provides a bridge to the vast array resources contained in the NCBI GEO repositories. By maintaining the full richness of the GEO data rather than focusing on getting only the “numbers”, it is possible to integrate GEO data into current Bioconductor data structures and to perform analyses on that data quite quickly and easily. These tools will hopefully open GEO data more fully to the array community at large.

## 7 sessionInfo
