`data.logicfs`

Example Data of logicFS

Description

`data.logicfs` contains two objects: a simulated matrix `data.logicfs` of 400 observations (rows) and 15 variables (columns) and a vector `cl.logicfs` of length 400 containing the class labels of the observations.

Each variable is categorical with realizations 1, 2 and 3. The first 200 observations are cases, the remaining are controls. If one of the following expression is `TRUE`, then the corresponding observation is a case:

`SNP1 == 3`

`SNP2 == 1 AND SNP4 == 3`

`SNP3 == 3 AND SNP5 == 3 AND SNP6 == 1`

where `SNP1` is in the first column of `data.logicfs`, `SNP2` in the second, and so on.

`getMatEval`

Evaluate Prime Implicants

Description

Computes the values of prime implicants for observations for which the values of the variables composing the prime implicants are available.

Usage

```
getMatEval(data, vec.primes, check = TRUE)
```

Arguments

<code>data</code>	a data frame in which each row corresponds to an observation, and each column to a binary variable.
<code>vec.primes</code>	a character vector naming the prime implicants that should be evaluated. Each of the variables composing these prime implicants must be represented by one column of <code>data</code> .
<code>check</code>	should some checks be done before the evaluation is performed? It is highly recommended not to change the default <code>check = TRUE</code> .

Value

a matrix in which each row corresponds to an observation (the same observations in the same order as in `data`, and each column to one of the prime implicants).

logic.bagging *Bagged Logic Regression*

Description

A bagging and subsampling version of logic regression. Currently available for the classification, the linear regression, and the logistic regression approach of `logreg`. Additionally, an approach based on multinomial logistic regressions as implemented in `mlogreg` can be used if the response is categorical.

Usage

```
## S3 method for class 'formula':
logic.bagging(formula, data, recdom = TRUE, ...)

## Default S3 method:
logic.bagging(x, y, B = 100, useN = TRUE, ntrees = 1, nleaves = 8,
  glm.if.1tree = FALSE, replace = TRUE, sub.frac = 0.632,
  anneal.control = logreg.anneal.control(), oob = TRUE,
  onlyRemove = FALSE, prob.case = 0.5, importance = TRUE,
  addMatImp = FALSE, fast = FALSE, rand = NULL, ...)
```

Arguments

<code>formula</code>	an object of class <code>formula</code> describing the model that should be fitted.
<code>data</code>	a data frame containing the variables in the model. Each row of <code>data</code> must correspond to an observation, and each column to a binary variable (coded by 0 and 1) or a factor (for details, see <code>recdom</code>) except for the column comprising the response. The response must be either binary (coded by 0 and 1), categorical or continuous. If continuous, a linear model is fitted in each of the <code>B</code> iterations of <code>logic.bagging</code> . If categorical, the column of <code>data</code> specifying the

response must be a factor. In this case, multinomial logic regressions are performed as implemented in `mlogreg`. Otherwise, depending on `ntrees` (and `glm.if.1tree`) the classification or the logistic regression approach of logic regression is used.

<code>recdom</code>	a logical value or vector of length <code>ncol(data)</code> comprising whether a SNP should be transformed into two binary dummy variables coding for a recessive and a dominant effect. If <code>TRUE</code> (logical value), then all factors (variables) with three levels will be coded by two dummy variables as described in <code>make.snp.dummy</code> . Each level of each of the other factors (also factors specifying a SNP that shows only two genotypes) is coded by one indicator variable. If <code>FALSE</code> (logical value), each level of each factor is coded by an indicator variable. If <code>recdom</code> is a logical vector, all factors corresponding to an entry in <code>recdom</code> that is <code>TRUE</code> are assumed to be SNPs and transformed into the two binary variables described above. Each variable that corresponds to an entry of <code>recdom</code> that is <code>TRUE</code> (no matter whether <code>recdom</code> is a vector or a value) must be coded by the integers 1 (coding for the homozygous reference genotype), 2 (heterozygous), and 3 (homozygous variant).
<code>x</code>	a matrix consisting of 0's and 1's. Each column must correspond to a binary variable and each row to an observation.
<code>y</code>	a numeric vector or a factor specifying the values of a response for all the observations represented in <code>x</code> . If a numeric vector, then <code>y</code> either contains the class labels (coded by 0 and 1) or the values of a continuous response depending on whether the classification or logistic regression approach of logic regression, or the linear regression approach, respectively, should be used. If the response is categorical, then <code>y</code> must be a factor naming the class labels of the observations.
<code>B</code>	an integer specifying the number of iterations.
<code>useN</code>	logical specifying if the number of correctly classified out-of-bag observations should be used in the computation of the importance measure. If <code>FALSE</code> , the proportion of correctly classified oob observations is used instead. Ignored if <code>importance = FALSE</code> .
<code>ntrees</code>	an integer indicating how many trees should be used. For a binary response: If <code>ntrees</code> is larger than 1, the logistic regression approach of logic regression will be used. If <code>ntrees</code> is 1, then by default the classification approach of logic regression will be used (see <code>glm.if.1tree</code> .) For a continuous response: A linear regression model with <code>ntrees</code> trees is fitted in each of the <code>B</code> iterations. For a categorical response: $n_{lev} - 1$ logic regression models with <code>ntrees</code> trees are fitted, where n_{lev} is the number of levels of the response (for details, see <code>mlogreg</code>).
<code>nleaves</code>	a numeric value specifying the maximum number of leaves used in all trees combined. See the help page of the function <code>logreg</code> of the package <code>LogicReg</code> for details.
<code>glm.if.1tree</code>	if <code>ntrees</code> is 1 and <code>glm.if.1tree</code> is <code>TRUE</code> the logistic regression approach of logic regression is used instead of the classification approach. Ignored if <code>ntrees</code> is not 1 or the response is not binary.
<code>replace</code>	should sampling of the cases be done with replacement? If <code>TRUE</code> , a bootstrap sample of size <code>length(c1)</code> is drawn from the <code>length(c1)</code> observations in each of the <code>B</code> iterations. If <code>FALSE</code> , <code>ceiling(sub.frac * length(c1))</code> of the observations are drawn without replacement in each iteration.

<code>sub.frac</code>	a proportion specifying the fraction of the observations that are used in each iteration to build a classification rule if <code>replace = FALSE</code> . Ignored if <code>replace = TRUE</code> .
<code>anneal.control</code>	a list containing the parameters for simulated annealing. See the help page of <code>logreg.aneal.control</code> in the <code>LogicReg</code> package.
<code>oob</code>	should the out-of-bag error rate (classification and logistic regression) or the out-of-bag root mean square prediction error (linear regression), respectively, be computed?
<code>onlyRemove</code>	should in the single tree case the multiple tree measure be used? If <code>TRUE</code> , the prime implicants are only removed from the trees when determining the importance in the single tree case. If <code>FALSE</code> , the original single tree measure is computed for each prime implicant, i.e. a prime implicant is not only removed from the trees in which it is contained, but also added to the trees that do not contain this interaction. Ignored in all other than the classification case.
<code>prob.case</code>	a numeric value between 0 and 1. If the outcome of the logistic regression, i.e. the class probability, for an observation is larger than <code>prob.case</code> , this observations will be classified as case (or 1).
<code>importance</code>	should the measure of importance be computed?
<code>addMatImp</code>	should the matrix containing the improvements due to the prime implicants in each of the iterations be added to the output? (For each of the prime implicants, the importance is computed by the average over the <code>B</code> improvements.) Must be set to <code>TRUE</code> , if standardized importances should be computed using <code>vim.norm</code> , or if permutation based importances should be computed using <code>vim.signperm</code> .
<code>fast</code>	should a greedy search (as implemented in <code>logreg</code>) be used instead of simulated annealing?
<code>rand</code>	numeric value. If specified, the random number generator will be set into a reproducible state.
<code>...</code>	for the <code>formula</code> method, optional parameters to be passed to the low level function <code>logic.bagging.default</code> . Otherwise, ignored.

Value

<code>logic.bagging</code>	returns an object of class <code>logicBagg</code> containing
<code>logreg.model</code>	a list containing the <code>B</code> logic regression models,
<code>inbagg</code>	a list specifying the <code>B</code> Bootstrap samples,
<code>vim</code>	an object of class <code>logicFS</code> (if <code>importance = TRUE</code>),
<code>oob.error</code>	the out-of-bag error (if <code>oob = TRUE</code>),
<code>...</code>	further parameters of the logic regression.

Examples

```
## Not run:
# Load data.
data(data.logicfs)

# For logic regression and hence logic.bagging, the variables must
# be binary. data.logicfs, however, contains categorical data
# with realizations 1, 2 and 3. Such data can be transformed
# into binary data by
bin.snps<-make.snp.dummy(data.logicfs)

# To speed up the search for the best logic regression models
# only a small number of iterations is used in simulated annealing.
my.anneal<-logreg.anneal.control(start=2,end=-2,iter=10000)

# Bagged logic regression is then performed by
bagg.out<-logic.bagging(bin.snps,cl.logicfs,B=20,nleaves=10,
  rand=123,anneal.control=my.anneal)

# The output of logic.bagging can be printed
bagg.out

# By default, also the importances of the interactions are
# computed
bagg.out$vim

# and can be plotted.
plot(bagg.out)

# The original variable names are displayed in
plot(bagg.out,coded=FALSE)

# New observations (here we assume that these observations are
# in data.logicfs) are assigned to one of the classes by
predict(bagg.out,data.logicfs)

## End(Not run)
```

Description

Identification of interesting interactions between binary variables using logic regression. Currently available for the classification, the linear regression and the logistic regression approach of `logreg` and for a multinomial logic regression as implemented in `mlogreg`.

Usage

```
## S3 method for class 'formula':
logicFS(formula, data, recdom = TRUE, ...)

## Default S3 method:
logicFS(x, y, B = 100, useN = TRUE, ntrees = 1, nleaves = 8,
  glm.if.1tree = FALSE, replace = TRUE, sub.frac = 0.632,
  anneal.control = logreg.anneal.control(), onlyRemove = FALSE,
  prob.case = 0.5, addMatImp = TRUE, fast = FALSE, rand = NULL, ...)
```

Arguments

<code>formula</code>	an object of class <code>formula</code> describing the model that should be fitted.
<code>data</code>	a data frame containing the variables in the model. Each row of <code>data</code> must correspond to an observation, and each column to a binary variable (coded by 0 and 1) or a factor (for details, see <code>recdom</code>) except for the column comprising the response. The response must be either binary (coded by 0 and 1), categorical or continuous. If continuous, a linear model is fitted in each of the <code>B</code> iterations of <code>logicFS</code> . If categorical, the column of <code>data</code> specifying the response must be a factor. In this case, multinomial logic regressions are performed as implemented in <code>mlogreg</code> . Otherwise, depending on <code>ntrees</code> (and <code>glm.if.1tree</code>) the classification or the logistic regression approach of logic regression is used.
<code>recdom</code>	a logical value or vector of length <code>ncol(data)</code> comprising whether a SNP should be transformed into two binary dummy variables coding for a recessive and a dominant effect. If <code>TRUE</code> (logical value), then all factors (variables) with three levels will be coded by two dummy variables as described in <code>make.snp.dummy</code> . Each level of each of the other factors (also factors specifying a SNP that shows only two genotypes) is coded by one indicator variable. If <code>FALSE</code> (logical value), each level of each factor is coded by an indicator variable. If <code>recdom</code> is a logical vector, all factors corresponding to an entry in <code>recdom</code> that is <code>TRUE</code> are assumed to be SNPs and transformed into the two binary variables described above. Each variable that corresponds to an entry of <code>recdom</code> that is <code>TRUE</code> (no matter whether <code>recdom</code> is a vector or a value) must be coded by the integers 1 (coding for the homozygous reference genotype), 2 (heterozygous), and 3 (homozygous variant).
<code>x</code>	a matrix consisting of 0's and 1's. Each column must correspond to a binary variable and each row to an observation.
<code>y</code>	a numeric vector or a factor specifying the values of a response for all the observations represented in <code>x</code> . If a numeric vector, then <code>y</code> either contains the class labels (coded by 0 and 1) or the values of a continuous response depending on whether the classification or logistic regression approach of logic regression, or the linear regression approach, respectively, should be used. If the response is categorical, then <code>y</code> must be a factor naming the class labels of the observations.
<code>B</code>	an integer specifying the number of iterations.

<code>useN</code>	logical specifying if the number of correctly classified out-of-bag observations should be used in the computation of the importance measure. If <code>FALSE</code> , the proportion of correctly classified oob observations is used instead.
<code>ntrees</code>	an integer indicating how many trees should be used. For a binary response: If <code>ntrees</code> is larger than 1, the logistic regression approach of logic regression will be used. If <code>ntrees</code> is 1, then by default the classification approach of logic regression will be used (see <code>glm.if.1tree</code>). For a continuous response: A linear regression model with <code>ntrees</code> trees is fitted in each of the <code>B</code> iterations. For a categorical response: $n.le\text{v} - 1$ logic regression models with <code>ntrees</code> trees are fitted, where $n.le\text{v}$ is the number of levels of the response (for details, see <code>mlogreg</code>).
<code>nleaves</code>	a numeric value specifying the maximum number of leaves used in all trees combined. For details, see the help page of the function <code>logreg</code> of the package <code>LogicReg</code> .
<code>glm.if.1tree</code>	if <code>ntrees</code> is 1 and <code>glm.if.1tree</code> is <code>TRUE</code> the logistic regression approach of logic regression is used instead of the classification approach. Ignored if <code>ntrees</code> is not 1, or the response is not binary.
<code>replace</code>	should sampling of the cases be done with replacement? If <code>TRUE</code> , a Bootstrap sample of size <code>length(c1)</code> is drawn from the <code>length(c1)</code> observations in each of the <code>B</code> iterations. If <code>FALSE</code> , <code>ceiling(sub.frac * length(c1))</code> of the observations are drawn without replacement in each iteration.
<code>sub.frac</code>	a proportion specifying the fraction of the observations that are used in each iteration to build a classification rule if <code>replace = FALSE</code> . Ignored if <code>replace = TRUE</code> .
<code>anneal.control</code>	a list containing the parameters for simulated annealing. See the help of the function <code>logreg.anneal.control</code> in the <code>LogicReg</code> package.
<code>onlyRemove</code>	should in the single tree case the multiple tree measure be used? If <code>TRUE</code> , the prime implicants are only removed from the trees when determining the importance in the single tree case. If <code>FALSE</code> , the original single tree measure is computed for each prime implicant, i.e. a prime implicant is not only removed from the trees in which it is contained, but also added to the trees that do not contain this interaction. Ignored in all other than the classification case.
<code>prob.case</code>	a numeric value between 0 and 1. If the outcome of the logistic regression, i.e. the predicted probability, for an observation is larger than <code>prob.case</code> this observations will be classified as case (or 1).
<code>addMatImp</code>	should the matrix containing the improvements due to the prime implicants in each of the iterations be added to the output? (For each of the prime implicants, the importance is computed by the average over the <code>B</code> improvements.) Must be set to <code>TRUE</code> , if standardized importances should be computed using <code>vim.norm</code> , or if permutation based importances should be computed using <code>vim.signperm</code> .
<code>fast</code>	should a greedy search (as implemented in <code>logreg</code>) be used instead of simulated annealing?
<code>rand</code>	numeric value. If specified, the random number generator will be set into a reproducible state.
<code>...</code>	for the <code>formula</code> method, optional parameters to be passed to the low level function <code>logicFS.default</code> . Otherwise, ignored.

Value

An object of class `logicFS` containing

<code>primes</code>	the prime implicants,
<code>vim</code>	the importance of the prime implicants,
<code>prop</code>	the proportion of logic regression models that contain the prime implicants,
<code>type</code>	the type of model (1: classification, 2: linear regression, 3: logistic regression),
<code>param</code>	further parameters (if <code>addInfo = TRUE</code>),
<code>mat.imp</code>	the matrix containing the improvements if <code>addMatImp = TRUE</code> , otherwise, <code>NULL</code> ,
<code>measure</code>	the name of the used importance measure,
<code>useN</code>	the value of <code>useN</code> ,
<code>threshold</code>	<code>NULL</code> ,
<code>mu</code>	<code>NULL</code> .

logic.oob

Prime Implicants

Description

Computes the out-of-bag error of the classification rule comprised by a `logicBagg` object.

Usage

```
logic.oob(log.out, prob.case = 0.5)
```

Arguments

<code>log.out</code>	an object of class <code>logicBagg</code> , i.e. the output of <code>logic.bagging</code> .
<code>prob.case</code>	a numeric value between 0 and 1. If the logic regression models are logistic regression models, i.e. if in <code>logic.bagging</code> <code>ntree</code> is set to a value larger than 1, or <code>glm.if.ltree</code> is set to <code>TRUE</code> , then an observation will be classified as case (or more exactly, as 1) if the class probability is larger than <code>prob.case</code> .

Value

The out-of-bag error estimate.

Author(s)

Holger Schwender, <holger.schwender@udo.edu>

[logic.bagging](#)

`logic.pimp`*Prime Implicants*

Description

Determines the prime implicants contained in the logic regression models comprised in an object of class `logicBagg`.

Usage

```
logic.pimp(log.out)
```

Arguments

`log.out` an object of class `logicBagg`, i.e. the output of `logic.bagging`.

Details

Since we are interested in all potentially interested interactions and not in a minimum set of them, `logic.pimp` and returns all prime implicants and not a minimum number of them.

Value

A list consisting of the prime implicants for each of the `B` logic regression models of `log.out`.

Author(s)

Holger Schwender, <holger.schwender@udo.edu>

See Also

[logic.bagging](#), [logicFS](#), [prime.implicants](#)

`make.snp.dummy`*SNPs to Dummy Variables*

Description

Transforms SNPs into binary dummy variables.

Usage

```
make.snp.dummy(data)
```

Arguments

`data` a matrix containing only 1's, 2's and 3's (see details). Each column of `data` corresponds to a SNP and each row to an observation.

Details

`make.snp.dummy` assumes that the homozygous dominant genotype is coded by 1, the heterozygous genotype by 2, and the homozygous recessive genotype by 3. For each SNP, 2 dummy variables are generated:

SNP.1 At least one of the bases explaining the SNP are of the recessive type.

SNP.2 Both bases are of the recessive type.

Value

A matrix with $2 * \text{ncol}(\text{data})$ columns containing 2 dummy variables for each SNP.

Note

See the R package `scime` for more general functions for recoding SNPs.

Author(s)

Holger Schwender, <holger.schwender@udo.edu>

minDNF

Minimum Disjunctive Normal Form

Description

Computes the prime implicants or the minimal disjunctive form, respectively, of a given truth table.

Usage

```
prime.implicants(mat)
minDNF(mat)
```

Arguments

`mat` a matrix containing only 0's and 1's. Each column of `mat` corresponds to a binary variable and each row to a combination of the variables for which the logic expression is TRUE.

Value

Either an object of class `minDNF` or of class `primeImp`. Both contain a vector of (a minimum number of) prime implicants. The `primeImp` additionally contains the prime implicant table.

mlogreg

Multinomial Logic Regression

Description

Performs a multinomial logic regression for a nominal response by fitting a logic regression model (with logit as link function) for each of the levels of the response except for the level with the smallest value which is used as reference category.

Usage

```
## S3 method for class 'formula':
mlogreg(formula, data, recdom = TRUE, ...)

## Default S3 method:
mlogreg(x, y, ntrees = 1, nleaves = 8, anneal.control = logreg.anneal.control(),
        select = 1, rand = NA, ...)
```

Arguments

formula	an object of class <code>formula</code> describing the model that should be fitted.
data	a data frame containing the variables in the model. Each column of <code>data</code> must correspond to a binary variable (coded by 0 and 1) or a factor (for details on factors, see <code>recdom</code>) except for the column comprising the response, and each row to an observation. The response must be a categorical variable with less than 10 levels. This response can be either a factor or of type <code>numeric</code> or <code>character</code> .
recdom	a logical value or vector of length <code>ncol(data)</code> comprising whether a SNP should be transformed into two binary dummy variables coding for a recessive and a dominant effect. If <code>TRUE</code> (logical value), then all factors (variables) with three levels will be coded by two dummy variables as described in make.snp.dummy . Each level of each of the other factors (also factors specifying a SNP that shows only two genotypes) is coded by one indicator variable. If <code>FALSE</code> (logical value), each level of each factor is coded by an indicator variable. If <code>recdom</code> is a logical vector, all factors corresponding to an entry in <code>recdom</code> that is <code>TRUE</code> are assumed to be SNPs and transformed into the two binary variables described above. Each variable that corresponds to an entry of <code>recdom</code> that is <code>TRUE</code> (no matter whether <code>recdom</code> is a vector or a value) must be coded by the integers 1 (coding for the homozygous reference genotype), 2 (heterozygous), and 3 (homozygous variant).
x	a matrix consisting of 0's and 1's. Each column must correspond to a binary variable and each row to an observation.
y	either a factor or a numeric or character vector specifying the values of the response. The length of <code>y</code> must be equal to the number of rows of <code>x</code> .
ntrees	an integer indicating how many trees should be used in the logic regression models. For details, see <code>logreg</code> in the <code>LogicReg</code> package.

nleaves	a numeric value specifying the maximum number of leaves used in all trees combined. See the help page of the function <code>logreg</code> in the <code>LogicReg</code> package for details.
anneal.control	a list containing the parameters for simulated annealing. For details, see the help page of <code>logreg.anneal.control</code> in the <code>LogicReg</code> package.
select	numeric value. Either 0 for a stepwise greedy selection (corresponds to <code>select = 6</code> in <code>logreg</code>) or 1 for simulated annealing.
rand	numeric value. If specified, the random number generator will be set into a reproducible state.
...	for the <code>formula</code> method, optional parameters to be passed to the low level function <code>mlogreg.default</code> . Otherwise, ignored.

Value

An object of class `mlogreg` composed of

model	a list containing the logic regression models,
data	a matrix containing the binary predictors,
cl	a vector comprising the class labels,
ntrees	a numeric value naming the maximum number of trees used in the logic regressions,
nleaves	a numeric value comprising the maximum number of leaves used in the logic regressions,
fast	a logical value specifying whether the faster search algorithm, i.e. the greedy search, has been used.

plot.logicFS *Variable Importance Plot*

Description

Generates a dotchart of the importance of the most important interactions for an object of class logicFS or logicBagg.

Usage

```
## S3 method for class 'logicFS':
plot(x, topX = 15, cex = 0.9, pch = 16, col = 1, show.prop = FALSE,
     force.topX = FALSE, coded = TRUE, add.thres = TRUE, thres = NULL,
     include0 = TRUE, add.v0 = TRUE, v0.col = "grey50", main = NULL, ...)

## S3 method for class 'logicBagg':
plot(x, topX = 15, cex = 0.9, pch = 16, col = 1, show.prop = FALSE,
     force.topX = FALSE, coded = TRUE, include0 = TRUE, add.v0 = TRUE,
     v0.col = "grey50", main = NULL, ...)
```

Arguments

x	an object of either class logicFS or logicBagg.
topX	integer specifying how many interactions should be shown. If topX is larger than the number of interactions contained in x all the interactions are shown. For further information, see force.topX.
cex	a numeric value specifying the relative size of the text and symbols.
pch	specifies the used symbol. See the help of par for details.
col	the color of the text and the symbols. See the help of par for how colors can be specified.
show.prop	if TRUE the proportions of models that contain the interactions of interest are shown. If FALSE (default) the importances of the interactions are shown.
force.topX	if TRUE exactly topX interactions are shown. If FALSE (default) all interactions up to the topXth most important one and all interactions having the same importance as the topXth most important one are shown.
coded	should the coded variable names be displayed? Might be useful if the actual variable names are pretty long. The coded variable name of the j-th variable is Xj.
add.thres	should a vertical line marking the threshold for a prime implicant to be called important be drawn in the plot? If TRUE, this vertical line will be drawn at NULL.
thres	non-negative numeric value specifying the threshold for a prime implicant to be called important. If NULL and add.thres = TRUE, the suggested threshold from x will be used.
include0	should the x-axis include zero regardless whether the importances of the shown interactions are much higher than 0?
add.v0	should a vertical line be drawn at x = 0? Ignored if include0 = FALSE and all importances are larger than zero.

v0.col	the color of the vertical line at $x = 0$. See the help page of <code>par</code> for how colors can be specified.
main	character string naming the title of the plot. If <code>NULL</code> , the name of the importance measure is used.
...	Ignored.

predict.logicBagg *Predict Method for logicBagg objects*

Description

Prediction for test data using an object of class `logicBagg`.

Usage

```
## S3 method for class 'logicBagg':
predict(object, newData, prob.case = 0.5,
        type = c("class", "prob"), ...)
```

Arguments

object	an object of class <code>logicBagg</code> .
newData	a matrix or data frame containing new data. If omitted <code>object\$data</code> , i.e. the original training data, are used. Each row of <code>newData</code> must correspond to a new observation. Each row of <code>newData</code> must contain the same variable as the corresponding column of the data matrix used in logic.bagging , i.e. x if the default method of logic.bagging has been used, or data <i>without</i> the column containing the response if the <code>formula</code> method has been used.
prob.case	a numeric value between 0 and 1. A new observation will be classified as case (or more exactly, as 1) if the class probability, i.e. the average of the predicted probabilities of the models (if the logistic regression approach of logic regression has been used), or the percentage of votes for class 1 (if the classification approach of logic regression has been used) is larger than <code>prob.case</code> . Ignored if <code>type = "prob"</code> or the response is quantitative.
type	character vector indicating the type of output. If <code>"class"</code> , a numeric vector of zeros and ones containing the predicted classes of the observations (using the specification of <code>prob.case</code>) will be returned. If <code>"prob"</code> , the class probabilities or percentages of votes for class 1, respectively, for all observations are returned. Ignored if the response is quantitative.
...	Ignored.

Value

A numeric vector containing the predicted classes (if `type = "class"`) or the class probabilities (if `type = "prob"`) of the new observations if the classification or the logistic regression approach of logic regression is used. If the response is quantitative, the predicted value of the response for all observations in the test data set is returned.

predict.mlogreg *Predict Method for mlogreg Objects*

Description

Prediction for test data using an object of class `mlogreg`.

Usage

```
## S3 method for class 'mlogreg':
predict(object, newData, type = c("class", "prob"), ...)
```

Arguments

<code>object</code>	an object of class <code>mlogreg</code> , i.e. the output of the function <code>mlogreg</code> .
<code>newData</code>	a matrix or data frame containing new data. If omitted <code>object\$data</code> , i.e. the original training data, are used. Each row of <code>newData</code> must correspond to a new observation. Each row of <code>newData</code> must contain the same variable as the corresponding column of the data matrix used in <code>mlogreg</code> , i.e. x if the default method of <code>mlogreg</code> has been used, or data <i>without</i> the column containing the response if the <code>formula</code> method has been used.
<code>type</code>	character vector indicating the type of output. If <code>"class"</code> , a vector containing the predicted classes of the observations will be returned. If <code>"prob"</code> , the class probabilities for each level and all observations are returned.
<code>...</code>	Ignored.

Value

A numeric vector containing the predicted classes (if `type = "class"`), or a matrix composed of the class probabilities (if `type = "prob"`).

print.logicFS *Print a logicFS object*

Description

Prints an object of class logicFS.

Usage

```
## S3 method for class 'logicFS':  
print(x, topX = 5, show.prop = TRUE, coded = FALSE, digits = 2, ...)
```

Arguments

x	an object of either class logicFS.
topX	integer indicating how many interactions should be shown. Additionally to the topX most important interactions, any interaction having the same importance as the topX most important one are also shown.
show.prop	should the proportions of models containing the interactions of interest also be shown?
coded	should the coded variable names be displayed? Might be useful if the actual variable names are pretty long. The coded variable name of the j -th variable is X_j .
digits	number of digits used in the output.
...	Ignored.

vim.chisq *ChiSquare Based Importance*

Description

Determining the importance of interactions found by `logic.bagging` or `logicFS` by Pearson's ChiSquare Statistic. Only available for the classification and the logistic regression approach of logic regression.

Usage

```
vim.chisq(object, data = NULL, cl = NULL)
```

Arguments

object	either an object of class <code>logicFS</code> or the output of an application of <code>logic.bagging</code> with <code>importance = TRUE</code> .
data	a data frame or matrix consisting of 0's and 1's in which each column corresponds to one of the explanatory variables used in the original analysis with <code>logic.bagging</code> or <code>logicFS</code> , and each row corresponds to an observation. Must be specified if <code>object</code> is an object of class <code>logicFS</code> , or <code>cl</code> is specified. If <code>object</code> is an object of class <code>logicBagg</code> and neither <code>data</code> nor <code>cl</code> is specified, <code>data</code> and <code>cl</code> stored in <code>object</code> is used to compute the ChiSquare statistics. It is, however, highly recommended to use new data to test the interactions contained in <code>object</code> , as they have been found using the data stored in <code>object</code> , and it is very likely that most of them will show up as interesting if they are tested on the same data set.
cl	a numeric vector of 0's and 1's specifying the class labels of the observations in <code>data</code> . Must be specified either if <code>object</code> is an object of class <code>logicFS</code> , or if <code>data</code> is specified.

Details

Currently Pearson's ChiSquare statistic is computed without continuity correction.

Contrary to `vim.logicFS` (and `vim.norm` and `vim.signperm`), `vim.chisq` does neither take the logic regression models into account nor uses the out-of-bag observations for computing the importances of the identified interactions. It "just" tests each of the found interactions on the whole data set by calculating Pearson's ChiSquare statistic for each of these interactions. It is, therefore, highly recommended to use an independent data set for specifying the importances of these interactions with `vim.chisq`.

Value

An object of class `logicFS` containing

<code>primes</code>	the prime implicants
<code>vim</code>	the values of Pearson's ChiSquare statistic,
<code>prop</code>	NULL,
<code>type</code>	NULL,
<code>param</code>	further parameters (if <code>object</code> is the output of <code>logicFS</code> or <code>vim.logicFS</code> with <code>addInfo = TRUE</code>),
<code>mat.imp</code>	NULL,
<code>measure</code>	"ChiSquare Based",
<code>threshold</code>	the 1 - 0.05/m quantile of the ChiSquare distribution with one degree of freedom,
<code>mu</code>	NULL.

Author(s)

Holger Schwender, <holger.schwender@udo.edu>

See Also

[logic.bagging](#), [logicFS](#), [vim.logicFS](#), [vim.norm](#), [vim.ebam](#)

Description

Determines the importance of interactions found by `logic.bagging` or `logicFS` by an Empirical Bayes Analysis of Microarrays (EBAM). Only available for the classification and the logistic regression approach of logic regression.

Usage

```
vim.ebam(object, data = NULL, cl = NULL, nameEBAM = NULL, ...)
```

Arguments

<code>object</code>	either an object of class <code>logicFS</code> or the output of an application of <code>logic.bagging</code> with <code>importance = TRUE</code> .
<code>data</code>	a data frame or matrix consisting of 0's and 1's in which each column corresponds to one of the explanatory variables used in the original analysis with <code>logic.bagging</code> or <code>logicFS</code> , and each row corresponds to an observation. Must be specified if <code>object</code> is an object of class <code>logicFS</code> , or <code>cl</code> is specified. If <code>object</code> is an object of class <code>logicBagg</code> and neither <code>data</code> nor <code>cl</code> is specified, <code>data</code> and <code>cl</code> stored in <code>object</code> is used to compute the ChiSquare statistics. It is, however, highly recommended to use new <code>data</code> to test the interactions contained in <code>object</code> , as they have been found using the <code>data</code> stored in <code>object</code> , and it is very likely that most of them will show up as interesting if they are tested on the same data set.
<code>cl</code>	a numeric vector of 0's and 1's specifying the class labels of the observations in <code>data</code> . Must be specified either if <code>object</code> is an object of class <code>logicFS</code> , or if <code>data</code> is specified.
<code>nameEBAM</code>	a character string. If specified, then the output of the EBAM analysis is stored under this name in the global environment.
<code>...</code>	further arguments of <code>ebam</code> and <code>cat.ebam</code> . For details, see the help files of these functions from the package <code>siggenes</code> .

Details

For each interaction found by `logic.bagging` or `logicFS`, the posterior probability that this interaction is significant is computed using the Empirical Bayes Analysis of Microarrays (EBAM). These posterior probabilities are used as the EBAM based importances of the interactions.

The test statistic underlying this EBAM analysis is Pearson's ChiSquare statistic. Currently, the value of this statistic is computed without continuity correction.

Contrary to `vim.logicFS` (and `vim.norm` and `vim.signperm`), `vim.ebam` does neither take the logic regression models into account nor uses the out-of-bag observations for computing the importances of the identified interactions. It "just" tests each of the found interactions on the whole data set by calculating Pearson's ChiSquare statistic for each of these interactions and performing an EBAM analysis. It is, therefore, highly recommended to use an independent data set for specifying the importances of these interactions with `vim.ebam`.

Value

An object of class `logicFS` containing

<code>primes</code>	the prime implicants,
<code>vim</code>	the posterior probabilities of the interactions,
<code>prop</code>	NULL,
<code>type</code>	NULL,
<code>param</code>	further parameters (if object is the output of <code>logicFS</code> or <code>vim.logicFS</code> with <code>addInfo = TRUE</code>),
<code>mat.imp</code>	NULL,
<code>measure</code>	"EBAM Based",
<code>threshold</code>	the value of <code>delta</code> used in the EBAM analysis (see help files for <code>ebam</code>); by default: 0.9,
<code>mu</code>	NULL.

vim.input

VIM for Inputs

Description

Quantifies the importance of each input variable occurring in at least one of the logic regression models found in the application of `logic.bagging`.

Usage

```
vim.input(object, useN = NULL, iter = NULL, prop = TRUE,
          standardize = FALSE, mu = 0, addMatImp = FALSE,
          prob.case = 0.5, rand = NA)
```

Arguments

object	an object of class <code>logicBagg</code> , i.e. the output of <code>logic.bagging</code>
useN	logical specifying if the number of correctly classified out-of-bag observations should be used in the computation of the importance measure. If <code>FALSE</code> , the proportion of correctly classified oob observations is used instead. If <code>NULL</code> (default), then the specification of <code>useN</code> in <code>object</code> is used.
iter	integer specifying the number of times the values of the considered variable are permuted in the computation of its importance. If <code>NULL</code> (default), the values of the variable are not permuted, but the variable is removed from the model.
prop	should the proportion of logic regression models containing the respective variable also be computed?
standardize	should a standardized version of the individual variable importance measure be returned? For details, see <code>mu</code> . In the linear regression case, <code>standardize = FALSE</code> should be used.
mu	a non-negative numeric value. Ignored if <code>standardize = FALSE</code> . Otherwise, a t-statistic for testing the null hypothesis that the importance of the respective variable is equal to <code>mu</code> is computed.
addMatImp	should the matrix containing the improvements due to each of the variables in each of the logic regression models be added to the output?
prob.case	a numeric value between 0 and 1. If the logistic regression approach of logic regression has been used in <code>logic.bagging</code> , then an observation will be classified as a case (or more exactly, as 1), if the class probability of this observation is larger than <code>prob.case</code> . Otherwise, <code>prob.case</code> is ignored.
rand	an integer for setting the random number generator in a reproducible case.

Value

An object of class `logicFS` containing

vim	the importances of the variables,
prop	the proportion of logic regression models containing the respective variable (if <code>prop = TRUE</code>) or <code>NULL</code> (if <code>prop = FALSE</code>),
primes	the names of the variables,
type	the type of model (1: classification, 2: linear regression, 3: logistic regression),
param	further parameters (if <code>addInfo = TRUE</code> in the previous call of <code>logic.bagging</code>),
mat.imp	either a matrix containing the improvements due to the variables for each of the models (if <code>addMatImp = TRUE</code>), or <code>NULL</code> (if <code>addMatImp = FALSE</code>),
measure	the name of the used importance measure,
useN	the value of <code>useN</code> ,
threshold	<code>NULL</code> if <code>standardize = FALSE</code> , otherwise the $1 - 0.05/m$ quantile of the t-distribution with $B - 1$ degrees of freedom, where m is the number of variables and B is the number of logic regression models composing <code>object</code> ,
mu	<code>mu</code> (if <code>standardize = TRUE</code>), or <code>NULL</code> (otherwise),
iter	<code>iter</code> .

vim.logicFS

Importance Measures

Description

Computes the value of the single or the multiple tree measure, respectively, for each prime implicant contained in a logic bagging model to specify the importance of the prime implicant for classification, if the response is binary. If the response is quantitative, the importance is specified by a measure based on the log2-transformed mean square prediction error.

Usage

```
vim.logicFS(log.out, useN = TRUE, onlyRemove = FALSE, prob.case = 0.5,
            addInfo = FALSE, addMatImp = TRUE)
```

Arguments

<code>log.out</code>	an object of class <code>logicBagg</code> , i.e. \ the output of <code>logic.bagging</code> .
<code>useN</code>	logical specifying if the number of correctly classified out-of-bag observations should be used in the computation of the importance measure. If <code>FALSE</code> , the proportion of correctly classified oob observations is used instead.
<code>onlyRemove</code>	should in the single tree case the multiple tree measure be used? If <code>TRUE</code> , the prime implicants are only removed from the trees when determining the importance in the single tree case. If <code>FALSE</code> , the original single tree measure is computed for each prime implicant, i.e. \ a prime implicant is not only removed from the trees in which it is contained, but also added to the trees that do not contain this interaction. Ignored in all other than the classification case.
<code>prob.case</code>	a numeric value between 0 and 1. If the logistic regression approach of logic regression is used (i.e. \ if the response is binary, and in <code>logic.bagging</code> <code>ntrees</code> is set to a value larger than 1, or <code>glm.if.ltree</code> is set to <code>TRUE</code>), then an observation will be classified as a case (or more exactly as 1), if the class probability of this observation estimated by the logic bagging model is larger than <code>prob.case</code> .
<code>addInfo</code>	should further information on the logic regression models be added?
<code>addMatImp</code>	should the matrix containing the improvements due to the prime implicants in each of the iterations be added to the output? (For each of the prime implicants, the importance is computed by the average over the <code>B</code> improvements.) Must be set to <code>TRUE</code> , if standardized importances should be computed using vim.norm , or if permutation based importances should be computed using vim.signperm .

Value

An object of class `logicFS` containing

<code>primes</code>	the prime implicants,
<code>vim</code>	the importance of the prime implicants,
<code>prop</code>	the proportion of logic regression models containing the prime implicants,
<code>type</code>	the type of model (1: classification, 2: linear regression, 3: logistic regression),
<code>param</code>	further parameters (if <code>addInfo = TRUE</code>),
<code>mat.imp</code>	the matrix containing the improvements if <code>addMatImp = TRUE</code> , otherwise, <code>NULL</code> ,
<code>measure</code>	the name of the used importance measure,
<code>useN</code>	the value of <code>useN</code> ,
<code>threshold</code>	<code>NULL</code> ,
<code>mu</code>	<code>NULL</code> .

vim.norm

Standardized and Sign-Permutation Based Importance Measure

Description

Computes a standardized or a sign-permutation based version of either the Single Tree Measure, the Quantitative Response Measure, or the Multiple Tree Measure.

Usage

```
vim.norm(object, mu = 0)
```

```
vim.signperm(object, mu = 0, n.perm = 10000, n.subset = 1000,
  adjust = "bonferroni", rand = NA)
```

Arguments

object	either the output of <code>logicFS</code> or <code>vim.logicFS</code> with <code>addMatImp = TRUE</code> , or the output of <code>logic.bagging</code> with <code>importance = TRUE</code> and <code>addMatImp = TRUE</code> .
mu	a non-negative numeric value. Default is zero. However, mu should actually be set to a value larger than zero. See <code>Details</code> .
n.perm	the number of sign permutations used in <code>vim.signperm</code> .
n.subset	an integer specifying how many permutations should be considered at once.
adjust	character vector naming the method with which the raw permutation based p-values are adjusted for multiplicity. If "qvalue", the function <code>qvalue.cal</code> from the package <code>siggenes</code> is used to compute q-values. Otherwise, <code>p.adjust</code> is used to adjust for multiple comparisons. See <code>p.adjust</code> for all other possible specifications of <code>adjust</code> . If "none", the raw p-values will be used. For more details, see <code>Details</code> .
rand	an integer for setting the random number generator in a reproducible case.

Details

In both `vim.norm` and `vim.signperm`, an one-sample t-statistic is computed for each prime implicant, where the numerator is given by $VIM - \mu$ with VIM being the single or the multiple tree importance, and the denominator is the corresponding standard error computed by employing the B improvements of the considered prime implicant in the B logic regression models, where VIM is the mean over these B improvements.

Note that in the case of a quantitative response, such a standardization is not necessary. Thus, `vim.norm` returns a warning when the response is quantitative, and `vim.signperm` does not divide $VIM - \mu$ by its sample standard error.

As using $\mu = 0$ might lead to calling a prime implicant important, even though it actually shows only improvements of 1 or 0, μ should be set to a value larger than zero.

In `vim.norm`, the value of this t-statistic is returned as the standardized importance of a prime implicant. The larger this value, the more important is the prime implicant. (This applies to all importance measures – at least for those contained in this package.) Assuming normality, a possible threshold for a prime implicant to be considered as important is the $1 - 0.05/m$ quantile of the t-distribution with $B - 1$ degrees of freedom, where m is the number of prime implicants.

In `vim.signperm`, the sign permutation is used to determine `n.perm` permuted values of the one-sample t-statistic, and to compute the raw p-values for each of the prime implicants. Afterwards, these p-values are adjusted for multiple comparisons using the method specified by `adjust`. The permutation based importance of a prime implicant is then given by $1 -$ these adjusted p-values. Here, a possible threshold for calling a prime implicant important is 0.95.

Value

An object of class `logicFS` containing

primes	the prime implicants,
vim	the respective importance of the prime implicants,
prop	NULL,
type	the type of model (1: classification, 2: linear regression, 3: logistic regression),
param	further parameters (if <code>addInfo = TRUE</code>),

mat.imp	NULL,
measure	the name of the used importance measure,
useN	the value of useN from the original analysis with, e.g., logicFS ,
threshold	the threshold suggested in Details,
mu	mu.

 vim.permSNP

Permutation Based Importance Measures

Description

Computes the importances of input variables, SNPs, or sets of SNPs, respectively, based on permutations of the response. Currently only available for the classification and the logistic regression approach of logic regression.

Usage

```
vim.permInput(object, n.perm = NULL, standardize = TRUE,
  rebuild = FALSE, prob.case = 0.5, useAll = FALSE,
  adjust = "bonferroni", addMatPerm = FALSE, rand=NA)
```

```
vim.permSNP(object, n.perm = NULL, standardize = TRUE,
  rebuild = FALSE, prob.case = 0.5, useAll = FALSE,
  adjust = "bonferroni", addMatPerm = FALSE, rand = NA)
```

```
vim.permSet(object, set = NULL, n.perm = NULL, standardize = TRUE,
  rebuild = FALSE, prob.case = 0.5, useAll = FALSE,
  adjust = "bonferroni", addMatPerm = FALSE, rand = NA)
```

Arguments

object	an object of class <code>logicBagg</code> , i.e.\ the output of logic.bagging .
set	either a list or a character or numeric vector. If <code>NULL</code> (default), then it will be assumed that <code>data</code> , i.e.\ the data set used in the application of logic.bagging , has been generated using make.snp.dummy or similar functions for coding variables by binary variables, i.e.\ with a function

that splits a variable, say SNP_x, into the dummy variables SNP_{x.1}, SNP_{x.2}, ... (where the "." can also be any other sign, e.g., an underscore).

If a character or a numeric vector, then the length of `set` must be equal to the number of variables used in `object`, i.e. the number of columns of `data` in the `logicBagg` object, and must specify the set to which a variable belongs either by an integer between 1 and the number of sets, or by a set name. If a variable should not be included in any of the sets, set the corresponding entry of `set` to NA. Using this specification of `set` it is not possible to assign a variable to more than one sets. For such a case, set `set` to a list (as follows).

If `set` is a list, then each object in this list represents a set of variables. Therefore, each object must be either a character or a numeric vector specifying either the names of the variables that belongs to the respective set or the columns of `data` that contains these variables. If `names(set)` is NULL, generic names will be employed as names for the sets. Otherwise, `names(set)` are used.

<code>n.perm</code>	number of permutations used in the computation of the importances. By default (i.e. if <code>n.perm = NULL</code>), 100 permutations are used if <code>rebuild = TRUE</code> and the regression approach of logic regression has been used in <code>logic.baggging</code> (by setting <code>ntrees</code> to an integer larger than 1, or <code>glm.if.ltree = TRUE</code>). Otherwise, 1000 permutation are employed. Note that actually much more permutations should be used.
<code>standardize</code>	should the standardized importance measure be used?
<code>rebuild</code>	logical indicating whether the logic regression models should be rebuild (i.e. the parameters β of the generalized linear models should be recomputed) after removing a variable or a set of variables from the logic trees and for each permutation of the response. Note that setting <code>rebuild = TRUE</code> increases the computation time substantially.
<code>prob.case</code>	a numeric value between 0 and 1. If the logistic regression approach of logic regression has been used in <code>logic.baggging</code> , then an observation will be classified as a case (or more exactly, as 1), if the class probability of this observation is larger than <code>prob.case</code> . Otherwise, <code>prob.case</code> is ignored.
<code>useAll</code>	logical indicating whether all $m * n.perm$ permuted values should be used in the computation of the permutation based p-values, where m is the number of variables or sets of variables, respectively. If FALSE, the <code>n.perm</code> permuted values corresponding to the respective variable (or set of variables) are employed in the determination of the p-value of this variable (or set of variables).
<code>adjust</code>	character vector naming the method with which the raw permutation based p-values are adjusted for multiplicity. If "qvalue", the function <code>qvalue.cal</code> from the package <code>siggenes</code> is used to compute q-values. Otherwise, <code>p.adjust</code> is used to adjust for multiple comparisons. See <code>p.adjust</code> for all other possible specifications of <code>adjust</code> . If "none", the raw p-values will be used.
<code>addMatPerm</code>	should the $(n.perm + 1) \times m$ matrix containing the original values (first column) and the permuted values (the remaining columns) of the importance measure for the m variables or m sets of variables be added to the output?
<code>rand</code>	an integer for setting the random number generator in a reproducible state.

Value

An object of class `logicFS` containing

`vim` the values of the importance measure for the input variables, the SNPs, or the sets of SNPs, respectively,

prop	NULL,
primes	the names of the inputs, SNPs, or sets of variables, respectively,
type	the type of model (1: classification, 3: logistic regression),
param	NULL,
mat.imp	NULL,
measure	the name of the used importance measure,
threshold	0.95, i.e.\ the suggested threshold for calling an input, SNP or set of SNPs, respectively, important (this is just used as default value when plotting the importances, see argument <code>thres</code> of <code>plot.logicFS</code>),
mu	NULL,
useN	TRUE,
name	either "Variable", "SNP", or "Set",
mat.perm	if <code>addMatPerm = FALSE</code> , NULL; otherwise, a matrix containing the original and the permuted values of the respective importance measure.

vim.set

VIM for SNPs and Sets of Variables

Description

Quantifies the importances of SNPs or sets of variables, respectively, contained in a logic bagging model.

Usage

```
vim.snp(object, useN = NULL, iter = NULL, standardize = FALSE,
        mu = 0, addMatImp = FALSE, prob.case = 0.5, rand = NA)
```

```
vim.set(object, set = NULL, useN = NULL, iter = NULL, standardize = FALSE,
        mu = 0, addMatImp = FALSE, prob.case = 0.5, rand = NA)
```

Arguments

<code>object</code>	an object of class <code>logicBagg</code> , i.e.\ the output of <code>logic.bagging</code> .
<code>set</code>	either a list or a character or numeric vector. If <code>NULL</code> (default), then it will be assumed that <code>data</code> , i.e.\ the data set used in the application of <code>logic.bagging</code> , has been generated using <code>make.snp.dummy</code> or similar functions for coding variables by binary variables, i.e.\ with a function that splits a variable, say <code>SNP_x</code> , into the dummy variables <code>SNP_x.1</code> , <code>SNP_x.2</code> , ... (where the "." can also be any other sign, e.g., an underscore). If a character or a numeric vector, then the length of <code>set</code> must be equal to the number of variables used in <code>object</code> , i.e.\ the number of columns of <code>data</code> in the <code>logicBagg</code> object, and must specify the set to which a variable belongs either by an integer between 1 and the number of sets, or by a set name. If a variable should not be included in any of the sets, set the corresponding entry of <code>set</code> to <code>NA</code> . Using this specification of <code>set</code> it is not possible to assign a variable to more than one sets. For such a case, set <code>set</code> to a list (as follows). If <code>set</code> is a list, then each object in this list represents a set of variables. Therefore, each object must be either a character or a numeric vector specifying either the names of the variables that belongs to the respective set or the columns of <code>data</code> that contains these variables. If <code>names(set)</code> is <code>NULL</code> , generic names will be employed as names for the sets. Otherwise, <code>names(set)</code> are used.
<code>useN</code>	logical specifying if the number of correctly classified out-of-bag observations should be used in the computation of the importance measure. If <code>FALSE</code> , the proportion of correctly classified oob observations is used instead. If <code>NULL</code> (default), then the specification of <code>useN</code> in <code>object</code> is used.
<code>iter</code>	integer specifying the number of times the values of the variables in the respective set are permuted in the computation of the importance of this set. If <code>NULL</code> (default), the values of the variables are not permuted, but all variables belonging to the set are removed from the model
<code>standardize</code>	should a standardized version of the importance measure for a set of variables be returned? For details, see <code>mu</code> . In the linear regression case, <code>standardize = TRUE</code> should be used.
<code>mu</code>	a non-negative numeric value. Ignored if <code>standardize = FALSE</code> . Otherwise, a t-statistic for testing the null hypothesis that the importance of the respective set is equal to <code>mu</code> is computed.
<code>addMatImp</code>	should the matrix containing the improvements due to each of the sets in each of the logic regression models be added to the output?
<code>prob.case</code>	a numeric value between 0 and 1. If the logistic regression approach of logic regression has been used in <code>logic.bagging</code> , then an observation will be classified as a case (or more exactly, as 1), if the class probability of this observation is larger than <code>prob.case</code> . Otherwise, <code>prob.case</code> is ignored.
<code>rand</code>	an integer for setting the random number generator in a reproducible state.

Value

An object of class <code>logicFS</code> containing	
<code>vim</code>	the importances of the sets of variables,
<code>prop</code>	<code>NULL</code> ,
<code>primes</code>	the names of the sets of variables,

type	the type of model (1: classification, 2:linear regression, 3: logistic regression),
param	further parameters (if <code>addInfo = TRUE</code> in the previous call of <code>logic.bagging</code>), or <code>NULL</code> (otherwise),
mat.imp	either a matrix containing the improvements due to the sets of variables for each of the models (if <code>addMatImp = TRUE</code>), or <code>NULL</code> (if <code>addMatImp = FALSE</code>),
measure	the name of the used importance measure,
threshold	<code>NULL</code> if <code>standardize = FALSE</code> , otherwise the $1 - 0.05/m$ quantile of the t-distribution with $B - 1$ degrees of freedom, where m is the number of sets and B is the number of logic regression models composing <code>object</code> ,
mu	mu (if <code>standardize = TRUE</code>), or <code>NULL</code> (otherwise),
iter	iter.
