

# Package ‘simplifyEnrichment’

April 12, 2022

**Type** Package

**Title** Simplify Functional Enrichment Results

**Version** 1.4.0

**Date** 2021-4-16

**Depends** R (>= 3.6.0), BiocGenerics, grid

**Imports** GOSemSim, ComplexHeatmap (>= 2.7.4), circlize, GetoptLong, digest, tm, GO.db, org.Hs.eg.db, AnnotationDbi, slam, methods, clue, grDevices, graphics, stats, utils, proxyC, Matrix, cluster (>= 1.14.2)

**Suggests** knitr, ggplot2, cowplot, mclust, apcluster, MCL, dbscan, igraph, gridExtra, dynamicTreeCut, testthat, gridGraphics, clusterProfiler, msigdb, DOSE, DO.db, reactome.db, flexclust, BiocManager, InteractiveComplexHeatmap (>= 0.99.11), shiny, shinydashboard, cola, hu6800.db, rmarkdown

## Description

A new clustering algorithm, binary cut, for clustering similarity matrices of functional terms is implemented in this package. It also provides functionalities for visualizing, summarizing and comparing the clusterings.

**biocViews** Software, Visualization, GO, Clustering, GeneSetEnrichment

**URL** <https://github.com/jokergoo/simplifyEnrichment>,  
<https://simplifyEnrichment.github.io>

**VignetteBuilder** knitr

**License** MIT + file LICENSE

**git\_url** <https://git.bioconductor.org/packages/simplifyEnrichment>

**git\_branch** RELEASE\_3\_14

**git\_last\_commit** 549d5f1

**git\_last\_commit\_date** 2021-10-26

**Date/Publication** 2022-04-12

**Author** Zuguang Gu [aut, cre] (<<https://orcid.org/0000-0002-7395-8709>>)

**Maintainer** Zuguang Gu <z.gu@dkfz.de>

all\_clustering\_methods  
*All clustering methods*

---

### Description

All clustering methods

### Usage

all\_clustering\_methods()

### Details

The default clustering methods are:

- kmeans see [cluster\\_by\\_kmeans](#).
- dynamicTreeCut see [cluster\\_by\\_dynamicTreeCut](#).
- mclust see [cluster\\_by\\_mclust](#).
- apcluster see [cluster\\_by\\_apcluster](#).
- hdbscan see [cluster\\_by\\_hdbscan](#).
- fast\_greedy see [cluster\\_by\\_igraph](#).
- leading\_eigen see [cluster\\_by\\_igraph](#).
- louvain see [cluster\\_by\\_igraph](#).
- walktrap see [cluster\\_by\\_igraph](#).
- MCL see [cluster\\_by\\_MCL](#).
- binary\_cut see [binary\\_cut](#).

### Value

A vector of method names.

### See Also

New methods can be added by [register\\_clustering\\_methods](#).

### Examples

```
all_clustering_methods()
```

---

anno\_word\_cloud      *Word cloud annotations*

---

## Description

Word cloud annotations

## Usage

```
anno_word_cloud(align_to, term, exclude_words = NULL, max_words = 10,
  word_cloud_grob_param = list(), fontsize_range = c(4, 16),
  bg_gp = gpar(fill = "#DDDDDD", col = "#AAAAAA"), side = c("right", "left"), ...)
```

## Arguments

align_to	How to align the annotations to the heatmap. Similar as in <a href="#">anno_link</a> , the value of align_to can be a list of row indices or a categorical vector where each vector in the list corresponds to a word cloud. If it is a categorical vector, rows with the same level correspond to a same word cloud. If align_to is a categorical vector and term is a list, names of term should have overlap to the levels in align_to. When align_to is set as a categorical vector, normally the same value is set to row_split in the main heatmap so that each row slice can correspond to a word cloud.
term	The description text used for constructing the word clouds. The value should have the same format as align_to. If align_to is a list, term should also be a list. In this case, the length of vectors in term is not necessarily the same as in align_to. E.g. length(term[[1]]) is not necessarily equal to length(align_to[[1]]). If align_to is a categorical vector, term should also be a character vector with the same length as align_to.
exclude_words	The words excluded for constructing word cloud.
max_words	Maximal number of words visualized in the word cloud.
word_cloud_grob_param	A list of graphics parameters passed to <a href="#">word_cloud_grob</a> .
fontsize_range	The range of the font size. The value should be a numeric vector with length two. The minimal font size is mapped to word frequency value of 1 and the maximal font size is mapped to the maximal word frequency. The font size interpolation is linear.
bg_gp	Graphics parameters for controlling the background.
side	Side of the annotation relative to the heatmap.
...	Other parameters.

## Details

The word cloud annotation is constructed by [anno\\_link](#).

If the annotation is failed to construct or no keyword is found, the function returns a [anno\\_empty](#) with 1px width.

**Examples**

```
gm = readRDS(system.file("extdata", "random_GO_BP_sim_mat.rds", package = "simplifyEnrichment"))
go_id = rownames(gm)
go_term = AnnotationDbi::select(GO.db::GO.db, keys = go_id, columns = "TERM")$TERM

split = sample(letters[1:4], 100, replace = TRUE)
align_to = split(1:100, split)
term = lapply(letters[1:4], function(x) sample(go_term, sample(100:400, 1)))
names(term) = letters[1:4]

require(ComplexHeatmap)
mat = matrix(rnorm(100*10), nrow = 100)
Heatmap(mat, cluster_rows = FALSE, row_split = split,
right_annotation = rowAnnotation(foo = anno_word_cloud(align_to, term)))
```

---

anno\_word\_cloud\_from\_GO

*Word cloud annotations from GO*

---

**Description**

Word cloud annotations from GO

**Usage**

```
anno_word_cloud_from_GO(align_to, go_id, term = NULL, exclude_words = NULL, ...)
```

**Arguments**

align_to	The same format as in <a href="#">anno_word_cloud</a> .
go_id	The value should be in the same format as align_to. If go_id is a vector, it should have the same length as align_to, and if go_id is a list, note, e.g. length(go_id[[1]]) is not necessarily equal to length(align_to[[1]]). If align_to is a categorical vector and go_id is a list, names of go_id should have overlap to the levels in align_to.
term	Alternatively the GO description can be set via the term argument. The same format as in <a href="#">anno_word_cloud</a> .
exclude_words	The words excluded for constructing word cloud. Some words are internally excluded: c("via", "protein", "factor", "side", "type", "specific").
...	All other arguments passed to <a href="#">anno_word_cloud</a> .

**Examples**

```
# There is no example
NULL
```

---

binary_cut	<i>Cluster functional terms by recursively binary cutting the similarity matrix</i>
------------	---

---

### Description

Cluster functional terms by recursively binary cutting the similarity matrix

### Usage

```
binary_cut(mat, value_fun = median, partition_fun = partition_by_pam,  
           cutoff = 0.85, try_all_partition_fun = FALSE, partial = FALSE)
```

### Arguments

mat	A similarity matrix.
value_fun	Value function to calculate the score for each node in the dendrogram.
partition_fun	A function to split each node into two groups. Pre-defined functions in this package are <a href="#">partition_by_kmeanspp</a> , <a href="#">partition_by_pam</a> and <a href="#">partition_by_hclust</a> .
cutoff	The cutoff for splitting the dendrogram.
try_all_partition_fun	Different partition_fun gives different clusterings. If the value of try_all_partition_fun is set to TRUE, the similarity matrix is clustered by three partitioning methods: <a href="#">partition_by_pam</a> , <a href="#">partition_by_kmeanspp</a> and <a href="#">partition_by_hclust</a> . The clustering with the highest difference score is finally selected as the final clustering.
partial	Whether to generate the complete clustering or the clustering stops when submatrices cannot be split anymore.

### Value

A vector of cluster labels (in numeric).

### Examples

```
mat = readRDS(system.file("extdata", "random_GO_BP_sim_mat.rds",  
                          package = "simplifyEnrichment"))  
binary_cut(mat)
```

---

cluster\_by\_apcluster *Cluster similarity matrix by apcluster*

---

**Description**

Cluster similarity matrix by apcluster

**Usage**

```
cluster_by_apcluster(mat, s = apcluster::negDistMat(r = 2), ...)
```

**Arguments**

mat	The similarity matrix.
s	Passed to the s argument in <a href="#">apcluster</a> .
...	Other arguments passed to <a href="#">apcluster</a> .

**Value**

A vector of cluster labels (in numeric).

**Examples**

```
# There is no example  
NULL
```

---

cluster\_by\_dynamicTreeCut  
*Cluster similarity matrix by dynamicTreeCut*

---

**Description**

Cluster similarity matrix by dynamicTreeCut

**Usage**

```
cluster_by_dynamicTreeCut(mat, minClusterSize = 5, ...)
```

**Arguments**

mat	The similarity matrix.
minClusterSize	Minimal number of objects in a cluster. Pass to <a href="#">cutreeDynamic</a> .
...	Other arguments passed to <a href="#">cutreeDynamic</a> .

**Value**

A vector of cluster labels (in numeric).

**Examples**

```
# There is no example  
NULL
```

---

cluster\_by\_hdbscan      *Cluster similarity matrix by hdbscan*

---

**Description**

Cluster similarity matrix by hdbscan

**Usage**

```
cluster_by_hdbscan(mat, minPts = 5, ...)
```

**Arguments**

mat	The similarity matrix.
minPts	Passed to the minPts argument in <a href="#">hdbscan</a> .
...	Other arguments passed to <a href="#">hdbscan</a> .

**Value**

A vector of cluster labels (in numeric).

**Examples**

```
# There is no example  
NULL
```

---

cluster_by_igraph	<i>Cluster similarity matrix by graph community detection methods</i>
-------------------	---

---

## Description

Cluster similarity matrix by graph community detection methods

## Usage

```
cluster_by_igraph(mat,  
  method = c("cluster_fast_greedy",  
    "cluster_leading_eigen",  
    "cluster_louvain",  
    "cluster_walktrap"),  
  ...)
```

## Arguments

mat	The similarity matrix.
method	The community detection method.
...	Other arguments passed to the corresponding community detection function, see Details.

## Details

The symmetric similarity matrix can be treated as an adjacency matrix and constructed as a graph/network with the similarity values as the weight of the edges. Thus, clustering the similarity matrix can be treated as detecting clusters/modules/communities from the graph.

Four methods implemented in igraph package can be used here:

```
cluster_fast_greedy uses cluster\_fast\_greedy.  
cluster_leading_eigen uses cluster\_leading\_eigen.  
cluster_louvain uses cluster\_louvain.  
cluster_walktrap uses cluster\_walktrap.
```

## Value

A vector of cluster labels (in numeric).

## Examples

```
# There is no example  
NULL
```

---

cluster\_by\_kmeans      *Cluster similarity matrix by k-means clustering*

---

**Description**

Cluster similarity matrix by k-means clustering

**Usage**

```
cluster_by_kmeans(mat, max_k = max(2, min(round(nrow(mat)/5), 100)), ...)
```

**Arguments**

mat	The similarity matrix.
max_k	maximal k for k-means clustering.
...	Other arguments passed to <a href="#">kmeans</a> .

**Details**

The best number of k for k-means clustering is identified according to the "elbow" or "knee" method on the distribution of within-cluster sum of squares (WSS) at each k.

**Value**

A vector of cluster labels (in numeric).

**Examples**

```
# There is no example  
NULL
```

---

cluster\_by\_MCL      *Cluster similarity matrix by MCL*

---

**Description**

Cluster similarity matrix by MCL

**Usage**

```
cluster_by_MCL(mat, addLoops = FALSE, ...)
```

**Arguments**

mat	The similarity matrix.
addLoops	Passed to the addLoops argument in <a href="#">mcl</a> .
...	Other arguments passed to <a href="#">mcl</a> .

**Value**

A vector of cluster labels (in numeric).

**Examples**

```
# There is no example
NULL
```

---

cluster_by_mclust	<i>Cluster similarity matrix by mclust</i>
-------------------	--

---

**Description**

Cluster similarity matrix by mclust

**Usage**

```
cluster_by_mclust(mat, G = seq_len(max(2, min(round(nrow(mat)/5), 100))), ...)
```

**Arguments**

mat	The similarity matrix.
G	Passed to the G argument in <a href="#">Mclust</a> .
...	Other arguments passed to <a href="#">Mclust</a> .

**Value**

A vector of cluster labels (in numeric).

**Examples**

```
# There is no example
NULL
```

---

cluster_terms	<i>Cluster functional terms</i>
---------------	---------------------------------

---

### Description

Cluster functional terms

### Usage

```
cluster_terms(mat, method = "binary_cut", control = list(), catch_error = FALSE,
              verbose = TRUE)
```

### Arguments

mat	A similarity matrix.
method	Method for clustering the matrix.
control	A list of parameters passed to the corresponding clustering function.
catch_error	Internally used.
verbose	Whether to print messages.

### Details

The following methods are the default:

kmeans see [cluster\\_by\\_kmeans](#).  
dynamicTreeCut see [cluster\\_by\\_dynamicTreeCut](#).  
mclust see [cluster\\_by\\_mclust](#).  
apcluster see [cluster\\_by\\_apcluster](#).  
hdbscan see [cluster\\_by\\_hdbscan](#).  
fast\_greedy see [cluster\\_by\\_igraph](#).  
leading\_eigen see [cluster\\_by\\_igraph](#).  
louvain see [cluster\\_by\\_igraph](#).  
walktrap see [cluster\\_by\\_igraph](#).  
MCL see [cluster\\_by\\_MCL](#).  
binary\_cut see [binary\\_cut](#).

Also the user-defined methods in [all\\_clustering\\_methods](#) can be used here.

New clustering methods can be registered by [register\\_clustering\\_methods](#).

Please note it is better to directly call [cluster\\_terms](#) for clustering while not the individual `cluster_by_*` functions because [cluster\\_terms](#) does additional cluster label adjustment.

**Value**

A numeric vector of cluster labels (in numeric).

If `catch_error` is set to `TRUE` and if the clustering produces an error, the function returns a `try-error` object.

**Examples**

```
# There is no example
NULL
```

---

cmp_make_clusters	<i>Apply various clustering methods</i>
-------------------	---

---

**Description**

Apply various clustering methods

**Usage**

```
cmp_make_clusters(mat, method = setdiff(all_clustering_methods(), "mclust"),
  verbose = TRUE)
```

**Arguments**

mat	The similarity matrix.
method	Which methods to compare. All available methods are in <a href="#">all_clustering_methods</a> . A value of <code>all</code> takes all available methods. By default <code>mclust</code> is excluded because its long runtime.
verbose	Whether to print messages.

**Details**

The function compares following default clustering methods by default:

`kmeans` see [cluster\\_by\\_kmeans](#).

`dynamicTreeCut` see [cluster\\_by\\_dynamicTreeCut](#).

`mclust` see [cluster\\_by\\_mclust](#). By default it is not included.

`apcluster` see [cluster\\_by\\_apcluster](#).

`hdbscan` see [cluster\\_by\\_hdbscan](#).

`fast_greedy` see [cluster\\_by\\_igraph](#).

`leading_eigen` see [cluster\\_by\\_igraph](#).

`louvain` see [cluster\\_by\\_igraph](#).

`walktrap` see [cluster\\_by\\_igraph](#).

MCL see [cluster\\_by\\_MCL](#).  
 binary\_cut see [binary\\_cut](#).

Also the user-defined methods in [all\\_clustering\\_methods](#) are also compared.

### Value

A list of cluster label vectors for different clustering methods.

### Examples

```
## Not run:
mat = readRDS(system.file("extdata", "random_GO_BP_sim_mat.rds",
  package = "simplifyEnrichment"))
clt = cmp_make_clusters(mat)

## End(Not run)
```

---

cmp_make_plot	<i>Make plots for comparing clustering methods</i>
---------------	--

---

### Description

Make plots for comparing clustering methods

### Usage

```
cmp_make_plot(mat, clt, plot_type = c("mixed", "heatmap"), nrow = 3)
```

### Arguments

mat	A similarity matrix.
clt	A list of clusterings from <a href="#">cmp_make_clusters</a> .
plot_type	What type of plots to make. See Details.
nrow	Number of rows of the layout when plot_type is set to heatmap.

### Details

If plot\_type is the default value mixed, a figure with three panels generated:

- A heatmap of the similarity matrix with different classifications as row annotations.
- A heatmap of the pair-wise concordance of the classifications of every two clustering methods.
- Barplots of the difference scores for each method (calculated by [difference\\_score](#)), the number of clusters (total clusters and the clusters with size  $\geq 5$ ) and the mean similarity of the terms that are in the same clusters.

If plot\_type is heatmap. There are heatmaps for the similarity matrix under clusterings from different methods. The last panel is a table with the number of clusters under different clusterings.

**Value**

No value is returned.

**Examples**

```
## Not run:
mat = readRDS(system.file("extdata", "random_GO_BP_sim_mat.rds",
  package = "simplifyEnrichment"))
clt = cmp_make_clusters(mat)
cmp_make_plot(mat, clt)
cmp_make_plot(mat, clt, plot_type = "heatmap")

## End(Not run)
```

---

compare\_clustering\_methods

*Compare clustering methods*

---

**Description**

Compare clustering methods

**Usage**

```
compare_clustering_methods(mat, method = setdiff(all_clustering_methods(), "mclust"),
  plot_type = c("mixed", "heatmap"), nrow = 3, verbose = TRUE)
```

**Arguments**

mat	The similarity matrix.
method	Which methods to compare. All available methods are in <a href="#">all_clustering_methods</a> . A value of all takes all available methods. By default mclust is excluded because its long runtime.
plot_type	See explanation in <a href="#">cmp_make_plot</a> .
nrow	Number of rows of the layout when plot_type is set to heatmap.
verbose	Whether to print messages.

**Details**

The function compares following clustering methods by default:

kmeans see [cluster\\_by\\_kmeans](#).

dynamicTreeCut see [cluster\\_by\\_dynamicTreeCut](#).

mclust see [cluster\\_by\\_mclust](#). By default it is not included.

apcluster see [cluster\\_by\\_apcluster](#).

hdbscan see [cluster\\_by\\_hdbscan](#).  
 fast\_greedy see [cluster\\_by\\_igraph](#).  
 leading\_eigen see [cluster\\_by\\_igraph](#).  
 louvain see [cluster\\_by\\_igraph](#).  
 walktrap see [cluster\\_by\\_igraph](#).  
 MCL see [cluster\\_by\\_MCL](#).  
 binary\_cut see [binary\\_cut](#).

This function is basically a wrapper function. It calls the following two functions:

- [cmp\\_make\\_clusters](#): applies clustering with different methods.
- [cmp\\_make\\_plot](#): makes the plots.

### Value

No value is returned.

### Examples

```

## Not run:
mat = readRDS(system.file("extdata", "random_GO_BP_sim_mat.rds",
  package = "simplifyEnrichment"))
compare_clustering_methods(mat)
compare_clustering_methods(mat, plot_type = "heatmap")

## End(Not run)

```

---

count\_word

*Calculate word frequency*

---

### Description

Calculate word frequency

### Usage

```
count_word(term, exclude_words = NULL)
```

### Arguments

term            A vector of description texts.  
 exclude\_words   The words that should be excluded.

### Details

The text preprocessing follows the instructions from <http://www.sthda.com/english/wiki/word-cloud-generator-in-r-one-killer-function-to-do-everything-you-need>.

**Value**

A data frame with words and frequencies.

**Examples**

```
gm = readRDS(system.file("extdata", "random_GO_BP_sim_mat.rds", package = "simplifyEnrichment"))
go_id = rownames(gm)
go_term = AnnotationDbi::select(GO.db::GO.db, keys = go_id, columns = "TERM")$TERM
count_word(go_term)
```

---

count\_word\_from\_GO      *Calculate word frequency From GO*

---

**Description**

Calculate word frequency From GO

**Usage**

```
count_word_from_GO(go_id, term = NULL, exclude_words = NULL)
```

**Arguments**

`go_id`                    A vector of GO IDs.  
`term`                    The corresponding names or description of terms if the input are not GO terms.  
`exclude_words`        The words that should be excluded.

**Details**

The input can be simply set with a vector of GO id to `go_id` argument so that the GO names are automatically extracted. Users can also provide a vector of long names/descriptions by `term` argument.

If the input is GO id, the following words are excluded: `c("via", "protein", "factor", "side", "type", "specific")`. They are analyzed by `simplifyEnrichment:::all_GO_word_count()`.

**Value**

A data frame with words and frequencies.

**See Also**

[count\\_word](#)

**Examples**

```
gm = readRDS(system.file("extdata", "random_GO_BP_sim_mat.rds", package = "simplifyEnrichment"))
go_id = rownames(gm)
head(count_word_from_GO(go_id))
```

---

dend\_node\_apply      *Apply functions on every node in a dendrogram*

---

### Description

Apply functions on every node in a dendrogram

### Usage

```
dend_node_apply(dend, fun)
```

### Arguments

dend	A dendrogram.
fun	A self-defined function.

### Details

The function returns a vector or a list as the same length as the number of nodes in the dendrogram. The self-defined function can have one single argument which is the sub-dendrogram at a certain node. E.g. to get the number of members at every node:

```
dend_node_apply(dend, function(d) attr(d, "members"))
```

The self-defined function can have a second argument, which is the index of current sub-dendrogram in the complete dendrogram. E.g. `dend[[1]]` is the first child node of the complete dendrogram and `dend[[c(1,2)]]` is the second child node of `dend[[1]]`, et al. This makes that at a certain node, it is possible to get information of its child nodes and parent nodes.

```
dend_node_apply(dend, function(d, index) {
  dend[[c(index, 1)]] # is the first child node of d, or simply d[[1]]
  dend[[index[-length(index)]]] # is the parent node of d
  ...
})
```

Note for the top node, the value of index is NULL.

### Value

A vector or a list, depends on whether fun returns a scalar or more complex values.

### Examples

```
mat = matrix(rnorm(100), 10)
dend = as.dendrogram(hclust(dist(mat)))
# number of members on every node
dend_node_apply(dend, function(d) attr(d, "members"))
# the depth on every node
dend_node_apply(dend, function(d, index) length(index))
```

---

difference_score	<i>Difference score</i>
------------------	-------------------------

---

**Description**

Difference score

**Usage**

```
difference_score(mat, cl)
```

**Arguments**

mat	The similarity matrix.
cl	Cluster labels.

**Details**

This function measures the different between the similarity values for the terms that belong to the same clusters and in different clusters. The difference score is the Kolmogorov-Smirnov statistic between the two distributions.

**Value**

A numeric scalar.

**Examples**

```
mat = readRDS(system.file("extdata", "random_GO_BP_sim_mat.rds",  
  package = "simplifyEnrichment"))  
cl = binary_cut(mat)  
difference_score(mat, cl)
```

---

DO_similarity	<i>Calculate Disease Ontology (DO) semantic similarity matrix</i>
---------------	---

---

**Description**

Calculate Disease Ontology (DO) semantic similarity matrix

**Usage**

```
DO_similarity(do_id, measure = "Rel")
```

**Arguments**

do\_id            A vector of DO IDs.  
 measure        Semantic measure for the DO similarity, pass to `doSim`.

**Details**

This function is basically a wrapper on `doSim`.

**Value**

A symmetric matrix.

**Examples**

```
require(DOSE)
do_id = random_DO(10)
DO_similarity(do_id)
```

---

edit_node	<i>Modify nodes in a dendrogram</i>
-----------	-------------------------------------

---

**Description**

Modify nodes in a dendrogram

**Usage**

```
edit_node(dend, fun = function(d, index) d)
```

**Arguments**

dend            A dendrogram.  
 fun            A self-defined function.

**Details**

if fun only has one argument, it is basically the same as `dendrapply`, but it can have a second argument which is the index of the node in the dendrogram, which makes it possible to get information of child nodes and parent nodes for a specific node.

As an example, we first assign random values to every node in the dendrogram:

```
mat = matrix(rnorm(100), 10)
dend = as.dendrogram(hclust(dist(mat)))
dend = edit_node(dend, function(d) {attr(d, 'score') = runif(1); d})
```

Then for every node, we take the maximal absolute difference to all its child nodes and parent node as the attribute `abs_diff`

```
dend = edit_node(dend, function(d, index) {
  n = length(index)
  s = attr(d, "score")
  if(is.null(index)) { # d is the top node
    s_children = sapply(d, function(x) attr(x, "score"))
    s_parent = NULL
  } else if(is.leaf(d)) { # d is the leaf
    s_children = NULL
    s_parent = attr(dend[[index[-n]]], "score")
  } else {
    s_children = sapply(d, function(x) attr(x, "score"))
    s_parent = attr(dend[[index[-n]]], "score")
  }
  abs_diff = max(abs(s - c(s_children, s_parent)))
  attr(d, "abs_diff") = abs_diff
  return(d)
})
```

### Value

A dendrogram object.

### Examples

```
# There is no example
NULL
```

---

export\_to\_shiny\_app *Interactively visualize the similarity heatmap*

---

### Description

Interactively visualize the similarity heatmap

### Usage

```
export_to_shiny_app(mat, cl = binary_cut(mat))
```

### Arguments

<code>mat</code>	A similarity matrix.
<code>cl</code>	Cluster labels inferred from the similarity matrix, e.g. from <code>cluster_terms</code> or <code>binary_cut</code> .

## Examples

```
mat = readRDS(system.file("extdata", "random_GO_BP_sim_mat.rds", package = "simplifyEnrichment"))
c1 = binary_cut(mat)
if(interactive()) {
  export_to_shiny_app(mat, c1)
}
```

---

GO\_similarity

*Calculate Gene Ontology (GO) semantic similarity matrix*

---

## Description

Calculate Gene Ontology (GO) semantic similarity matrix

## Usage

```
GO_similarity(go_id, ont = NULL, db = 'org.Hs.eg.db', measure = "Rel")
```

## Arguments

go_id	A vector of GO IDs.
ont	GO ontology. Value should be one of "BP", "CC" or "MF". If it is not specified, the function automatically identifies it by random sampling 10 IDs from go_id (see <a href="#">guess_ont</a> ).
db	Annotation database. It should be from <a href="https://bioconductor.org/packages/3.10/BiocViews.html#___OrgDb">https://bioconductor.org/packages/3.10/BiocViews.html#___OrgDb</a>
measure	Semantic measure for the GO similarity, pass to <a href="#">termSim</a> .

## Details

This function is basically a wrapper on [termSim](#).

## Value

A symmetric matrix.

## Examples

```
go_id = random_GO(100)
mat = GO_similarity(go_id)
```

---

guess_ont	<i>Guess the ontology of the input GO IDs</i>
-----------	---

---

**Description**

Guess the ontology of the input GO IDs

**Usage**

```
guess_ont(go_id, db = 'org.Hs.eg.db')
```

**Arguments**

go_id	A vector of GO IDs.
db	Annotation database. It should be from <a href="https://bioconductor.org/packages/3.10/BiocViews.html#___OrgDb">https://bioconductor.org/packages/3.10/BiocViews.html#___OrgDb</a>

**Details**

10 GO IDs are randomly sampled and checked.

**Value**

A single character scalar of "BP", "CC" or "MF".  
If there are more than one ontologies detected. It returns NULL.

**Examples**

```
go_id = random_GO(100)  
guess_ont(go_id)
```

---

heightDetails.word_cloud	<i>Height for word_cloud grob</i>
--------------------------	-----------------------------------

---

**Description**

Height for word\_cloud grob

**Usage**

```
## S3 method for class 'word_cloud'  
heightDetails(x)
```

**Arguments**

x                    The word\_cloud grob returned by `word_cloud_grob`.

**Value**

A `unit` object.

**Examples**

```
# There is no example
NULL
```

---

ht\_clusters

*Visualize the similarity matrix and the clustering*

---

**Description**

Visualize the similarity matrix and the clustering

**Usage**

```
ht_clusters(
  mat,
  cl,
  dend = NULL,
  col = c("white", "red"),

  # arguments that control the word cloud annotation
  draw_word_cloud = is_GO_id(rownames(mat)[1]) || !is.null(term),
  term = NULL,
  min_term = round(nrow(mat)*0.01),
  order_by_size = FALSE,
  exclude_words = character(0),
  max_words = 10,
  word_cloud_grob_param = list(),
  fontsize_range = c(4, 16),
  bg_gp = gpar(fill = "#DDDDDD", col = "#AAAAAA"),

  # arguments that control the heatmaps
  column_title = NULL,
  ht_list = NULL,
  use_raster = TRUE,
  run_draw = TRUE,
  ...)
```

**Arguments**

mat	A similarity matrix.
cl	Cluster labels inferred from the similarity matrix, e.g. from <a href="#">cluster_terms</a> or <a href="#">binary_cut</a> .
dend	Used internally.
col	A vector of colors that map from 0 to the 95 <sup>th</sup> percentile of the similarity values.
draw_word_cloud	Whether to draw the word clouds.
term	The full name or the description of the corresponding GO IDs.
min_term	Minimal number of functional terms in a cluster. All the clusters with size less than <code>min_term</code> are all merged into one separated cluster in the heatmap.
order_by_size	Whether to reorder clusters by their sizes. The cluster that is merged from small clusters ( <code>size &lt; min_term</code> ) is always put to the bottom of the heatmap.
exclude_words	Words that are excluded in the word cloud.
max_words	Maximal number of words visualized in the word cloud.
word_cloud_grob_param	A list of graphic parameters passed to <a href="#">word_cloud_grob</a> .
fontsize_range	The range of the font size. The value should be a numeric vector with length two. The minimal font size is mapped to word frequency value of 1 and the maximal font size is mapped to the maximal word frequency. The font size interpolation is linear.
bg_gp	Graphics parameters for controlling word cloud annotation background.
column_title	Column title for the heatmap.
ht_list	A list of additional heatmaps added to the left of the similarity heatmap.
use_raster	Whether to write the heatmap as a raster image.
run_draw	Internally used.
...	Other arguments passed to <a href="#">draw, HeatmapList-method</a> .

**Value**

A [HeatmapList-class](#) object.

**Examples**

```
mat = readRDS(system.file("extdata", "random_GO_BP_sim_mat.rds",
  package = "simplifyEnrichment"))
cl = binary_cut(mat)
ht_clusters(mat, cl, word_cloud_grob_param = list(max_width = 80))
ht_clusters(mat, cl, word_cloud_grob_param = list(max_width = 80),
  order_by_size = TRUE)
```

partition\_by\_hclust    *Partition by hclust*

---

**Description**

Partition by hclust

**Usage**

```
partition_by_hclust(mat)
```

**Arguments**

mat                    The similarity matrix.

**Details**

The "ward.D2" clustering method was used.

This function is used to set to the `partition_fun` argument in [binary\\_cut](#).

**Examples**

```
# There is no example  
NULL
```

---

partition\_by\_kmeans    *Partition by kmeans*

---

**Description**

Partition by kmeans

**Usage**

```
partition_by_kmeans(mat, n_repeats = 10)
```

**Arguments**

mat                    The similarity matrix.  
n\_repeats              Number of repeated runs of k-means.

**Details**

Since k-means clustering brings randomness, this function performs k-means clustering several times and uses the final consensus partitioning.

This function is used to set to the `partition_fun` argument in [binary\\_cut](#).

**Examples**

```
# There is no example  
NULL
```

---

`partition_by_kmeanspp` *Partition by kmeans++*

---

**Description**

Partition by kmeans++

**Usage**

```
partition_by_kmeanspp(mat)
```

**Arguments**

mat                    The similarity matrix.

**Details**

This function is used to set to the `partition_fun` argument in [binary\\_cut](#).

**Examples**

```
# There is no example  
NULL
```

---

`partition_by_pam`        *Partition by PAM*

---

**Description**

Partition by PAM

**Usage**

```
partition_by_pam(mat)
```

**Arguments**

mat                    The similarity matrix.

**Details**

The clustering is performed by [pam](#) with setting pamonce argument to 5.

This function is used to set to the partition\_fun argument in [binary\\_cut](#).

**Examples**

```
# There is no example
NULL
```

---

plot_binary_cut	<i>Visualize the process of binary cut</i>
-----------------	--

---

**Description**

Visualize the process of binary cut

**Usage**

```
plot_binary_cut(mat, value_fun = median, cutoff = 0.85,
  partition_fun = partition_by_pam, dend = NULL, dend_width = unit(3, "cm"),
  depth = NULL, show_heatmap_legend = TRUE, ...)
```

**Arguments**

mat	The similarity matrix.
value_fun	Value function to calculate the score for each node in the dendrogram.
cutoff	The cutoff for splitting the dendrogram.
partition_fun	A function to split each node into two groups. Pre-defined functions in this package are <a href="#">partition_by_kmeanspp</a> , <a href="#">partition_by_pam</a> and <a href="#">partition_by_hclust</a> .
dend	A dendrogram object, used internally.
depth	Depth of the recursive binary cut process.
dend_width	Width of the dendrogram.
show_heatmap_legend	Whether to show the heatmap legend.
...	Other arguments.

**Details**

After the functions which performs clustering are executed, such as [simplifyGO](#) or [binary\\_cut](#), the dendrogram is temporarily saved and [plot\\_binary\\_cut](#) directly uses this dendrogram. So, if the partition function brings randomness, it makes sure the clustering is the same as the one made by e.g. [simplifyGO](#).

**Examples**

```
mat = readRDS(system.file("extdata", "random_GO_BP_sim_mat.rds",
  package = "simplifyEnrichment"))
plot_binary_cut(mat, depth = 1)
plot_binary_cut(mat, depth = 2)
plot_binary_cut(mat)
```

---

random_DO	<i>Generate random Disease Ontology (DO) IDs</i>
-----------	--

---

**Description**

Generate random Disease Ontology (DO) IDs

**Usage**

```
random_DO(n)
```

**Arguments**

n	Number of DO IDs.
---	-------------------

**Details**

DO.db package should be installed.

**Value**

A vector of DO IDs.

**Examples**

```
random_DO(100)
```

---

random_GO	<i>Generate random GO IDs</i>
-----------	-------------------------------

---

**Description**

Generate random GO IDs

**Usage**

```
random_GO(n, ont = "BP", db = 'org.Hs.eg.db')
```

**Arguments**

n	Number of GO IDs.
ont	GO ontology. Value should be one of "BP", "CC" or "MF".
db	Annotation database. It should be from <a href="https://bioconductor.org/packages/3.10/BiocViews.html#___OrgDb">https://bioconductor.org/packages/3.10/BiocViews.html#___OrgDb</a>

**Value**

A vector of GO IDs.

**Examples**

```
random_GO(100)
```

---

register_clustering_methods	<i>Register new clustering methods</i>
-----------------------------	--

---

**Description**

Register new clustering methods

**Usage**

```
register_clustering_methods(...)
```

**Arguments**

...	A named list of clustering functions, see Details.
-----	--

**Details**

The user-defined functions should accept at least one argument which is the input matrix. The second optional argument should always be `...` so that parameters for the clustering function can be passed by control argument from `cluster_terms`, `simplifyGO` or `simplifyEnrichment`. If users forget to add `...`, it is added internally.

Please note, the user-defined function should automatically identify the optimized number of clusters.

The function should return a vector of cluster labels. Internally it is converted to numeric labels.

**Value**

No value is returned.

**Examples**

```
register_clustering_methods(  
# assume there are 5 groups  
random = function(mat, ...) sample(5, nrow(mat), replace = TRUE)  
)  
all_clustering_methods()  
remove_clustering_methods("random")
```

---

```
remove_clustering_methods  
      Remove clustering methods
```

---

**Description**

Remove clustering methods

**Usage**

```
remove_clustering_methods(method)
```

**Arguments**

method            A vector of method names.

**Value**

No value is returned.

**Examples**

```
# There is no example  
NULL
```

---

`reset_clustering_methods`*Reset to default clustering methods*

---

**Description**

Reset to default clustering methods

**Usage**

```
reset_clustering_methods()
```

**Details**

The default methods are:

kmeans see [cluster\\_by\\_kmeans](#).

dynamicTreeCut see [cluster\\_by\\_dynamicTreeCut](#).

mclust see [cluster\\_by\\_mclust](#).

apcluster see [cluster\\_by\\_apcluster](#).

hdbscan see [cluster\\_by\\_hdbscan](#).

fast\_greedy see [cluster\\_by\\_igraph](#).

leading\_eigen see [cluster\\_by\\_igraph](#).

louvain see [cluster\\_by\\_igraph](#).

walktrap see [cluster\\_by\\_igraph](#).

MCL see [cluster\\_by\\_MCL](#).

binary\_cut see [binary\\_cut](#).

**Value**

No value is returned.

**Examples**

```
all_clustering_methods()
remove_clustering_methods(c("kmeans", "mclust"))
all_clustering_methods()
reset_clustering_methods()
all_clustering_methods()
```

---

scale_fontsize	<i>Scale font size</i>
----------------	------------------------

---

**Description**

Scale font size

**Usage**

```
scale_fontsize(x, rg = c(1, 30), fs = c(4, 16))
```

**Arguments**

x	A numeric vector.
rg	The range.
fs	Range of the font size.

**Value**

A numeric vector.

**Details**

It is a linear interpolation.

**Examples**

```
x = runif(10, min = 1, max = 20)
# scale x to fontsize 4 to 16.
scale_fontsize(x)
```

---

select_cutoff	<i>Select the cutoff for binary cut</i>
---------------	---

---

**Description**

Select the cutoff for binary cut

**Usage**

```
select_cutoff(mat, cutoff = seq(0.6, 0.98, by = 0.01), verbose = TRUE, ...)
```

**Arguments**

mat	A similarity matrix.
cutoff	A list of cutoffs to test. Note the range of the cutoff values should be inside [0.5, 1].
verbose	Whether to print messages.
...	Pass to <a href="#">binary_cut</a> .

**Details**

Binary cut is applied to each of the cutoff and the clustering results are evaluated by following metrics:

- difference score, calculated by [difference\\_score](#).
- number of clusters.
- block mean, which is the mean similarity in the blocks in the diagonal of the heatmap.

**Examples**

```
mat = readRDS(system.file("extdata", "random_GO_BP_sim_mat.rds",
  package = "simplifyEnrichment"))
select_cutoff(mat)
```

---

simplifyEnrichment      *Simplify functional enrichment results*

---

**Description**

Simplify functional enrichment results

**Usage**

```
simplifyEnrichment(mat, method = "binary_cut", control = list(),
  plot = TRUE, term = NULL, verbose = TRUE,
  column_title = qq("@{nrow(mat)} terms clustered by '{@method}'"),
  ht_list = NULL, ...)
```

**Arguments**

mat	A similarity matrix.
method	Method for clustering the matrix. See <a href="#">cluster_terms</a> .
control	A list of parameters for controlling the clustering method, passed to <a href="#">cluster_terms</a> .
plot	Whether to make the heatmap.
term	The full name or the description of the corresponding terms.

column_title	Column title for the heatmap.
verbose	Whether to print messages.
ht_list	A list of additional heatmaps added to the left of the similarity heatmap.
...	Arguments passed to <a href="#">ht_clusters</a> .

### Details

The usage is the same as [simplifyGO](#), except you need to manually provide the term names by term argument if you want to draw the word clouds.

### Examples

```
# There is no example
NULL
```

---

simplifyGO	<i>Simplify Gene Ontology (GO) enrichment results</i>
------------	---

---

### Description

Simplify Gene Ontology (GO) enrichment results

### Usage

```
simplifyGO(mat, method = "binary_cut", control = list(),
  plot = TRUE, term = NULL, verbose = TRUE,
  column_title = qq("@{nrow(mat)} GO terms clustered by '{method}'"),
  ht_list = NULL, ...)
```

### Arguments

mat	A GO similarity matrix.
method	Method for clustering the matrix. See <a href="#">cluster_terms</a> .
control	A list of parameters for controlling the clustering method, passed to <a href="#">cluster_terms</a> .
plot	Whether to make the heatmap.
term	The full name or the description of the corresponding GO IDs. The values are automatically extracted if it is not provided.
column_title	Column title for the heatmap.
verbose	Whether to print messages.
ht_list	A list of additional heatmaps added to the left of the similarity heatmap.
...	Arguments passed to <a href="#">ht_clusters</a> .

## Details

This is basically a wrapper function that it first runs `cluster_terms` to cluster GO terms and then runs `ht_clusters` to visualize the clustering.

The arguments in `simplifyGO` passed to `ht_clusters` are:

`draw_word_cloud` Whether to draw the word clouds.

`min_term` Minimal number of GO terms in a cluster. All the clusters with size less than `min_term` are all merged into one single cluster in the heatmap.

`order_by_size` Whether to reorder GO clusters by their sizes. The cluster that is merged from small clusters (`size < min_term`) is always put to the bottom of the heatmap.

`exclude_words` Words that are excluded in the word cloud.

`max_words` Maximal number of words visualized in the word cloud.

`word_cloud_grob_param` A list of graphic parameters passed to `word_cloud_grob`.

`fontsize_range` The range of the font size. The value should be a numeric vector with length two. The minimal font size is mapped to word frequency value of 1 and the maximal font size is mapped to the maximal word frequency. The font size interpolation is linear.

`bg_gp` Graphic parameters for controlling the background of word cloud annotations.

## Value

A data frame with three columns: GO IDs, GO term names and cluster labels.

## See Also

[simplifyGOFromMultipleLists](#) which performs `simplifyGO` analysis with multiple lists of GO IDs.

## Examples

```
set.seed(123)
go_id = random_GO(500)
mat = GO_similarity(go_id)
df = simplifyGO(mat, word_cloud_grob_param = list(max_width = 80))
head(df)
```

---

`simplifyGOFromMultipleLists`

*Perform simplifyGO analysis with multiple lists of GO IDs*

---

## Description

Perform `simplifyGO` analysis with multiple lists of GO IDs

**Usage**

```
simplifyGOFromMultipleLists(lt, go_id_column = NULL, padj_column = NULL, padj_cutoff = 1e-2,
  filter = function(x) any(x < padj_cutoff), default = 1,
  ont = NULL, db = 'org.Hs.eg.db', measure = "Rel",
  heatmap_param = list(NULL),
  method = "binary_cut", control = list(partial = TRUE),
  min_term = NULL, verbose = TRUE, column_title = NULL, ...)
```

**Arguments**

lt	A data frame, a list of numeric vectors (e.g. adjusted p-values) where each numeric vector has GO IDs as names, or a list of GO IDs.
go_id_column	Column index of GO ID if lt contains a list of data frames.
padj_column	Column index of adjusted p-values if lt contains a list of data frames.
padj_cutoff	Cut off for adjusted p-values
filter	A self-defined function for filtering GO IDs. By default it requires GO IDs should be significant in at least one list.
default	The default value for the adjusted p-values. See Details.
ont	GO ontology. Value should be one of "BP", "CC" or "MF". If it is not specified, the function automatically identifies it by random sampling 10 IDs from go_id (see <a href="#">guess_ont</a> ).
db	Annotation database. It should be from <a href="https://bioconductor.org/packages/3.10/BiocViews.html#___OrgDb">https://bioconductor.org/packages/3.10/BiocViews.html#___OrgDb</a>
measure	Semantic measure for the GO similarity, pass to <a href="#">termSim</a> .
heatmap_param	Parameters for controlling the heatmap, see Details.
method	Pass to <a href="#">simplifyGO</a> .
control	Pass to <a href="#">simplifyGO</a> .
min_term	Pass to <a href="#">simplifyGO</a> .
verbose	Pass to <a href="#">simplifyGO</a> .
column_title	Pass to <a href="#">simplifyGO</a> .
...	Pass to <a href="#">simplifyGO</a> .

**Details**

The input data can have three types of formats:

- A list of numeric vectors of adjusted p-values where each vector has the GO IDs as names.
- A data frame. The column of the GO IDs can be specified with go\_id\_column argument and the column of the adjusted p-values can be specified with padj\_column argument. If these columns are not specified, they are automatically identified. The GO ID column is found by checking whether a column contains all GO IDs. The adjusted p-value column is found by comparing the column names of the data frame to see whether it might be a column for adjusted p-values. These two columns are used to construct a numeric vector with GO IDs as names.

- A list of character vectors of GO IDs. In this case, each character vector is changed to a numeric vector where all values take 1 and the original GO IDs are used as names of the vector.

Now let's assume there are  $n$  GO lists, we first construct a global matrix where columns correspond to the  $n$  GO lists and rows correspond to the "union" of all GO IDs in the lists. The value for the  $i$ th GO ID and in the  $j$ th list are taken from the corresponding numeric vector in  $lt$ . If the  $j$ th vector in  $lt$  does not contain the  $i$ th GO ID, the value defined by default argument is taken there (e.g. in most cases the numeric values are adjusted p-values, default is set to 1). Let's call this matrix as  $M_0$ .

Next step is to filter  $M_0$  so that we only take a subset of GO IDs of interest. We define a proper function via argument `filter` to remove GO IDs that are not important for the analysis. Functions for `filter` is applied to every row in  $M_0$  and `filter` function needs to return a logical value to decide whether to remove the current GO ID. For example, if the values in  $lt$  are adjusted p-values, the `filter` function can be set as `function(x) any(x < padj_cutoff)` so that the GO ID is kept as long as it is significant in at least one list. After the filter, let's call the filtered matrix  $M_1$ .

GO IDs in  $M_1$  (row names of  $M_1$ ) are used for clustering. A heatmap of  $M_1$  is attached to the left of the GO similarity heatmap so that the group-specific (or list-specific) patterns can be easily observed and to corresponded to GO functions.

Argument `heatmap_param` controls several parameters for heatmap  $M_1$ :

- `transform`: A self-defined function to transform the data for heatmap visualization. The most typical case is to transform adjusted p-values by  $-\log_{10}(x)$ .
- `breaks`: break values for color interpolation.
- `col`: The corresponding values for breaks.
- `labels`: The corresponding labels.
- `name`: Legend title.

## Examples

```
# perform functional enrichment on the signatures genes from cola analysis
require(cola)
data(golub_cola)
res = golub_cola["ATC:skmeans"]
require(hu6800.db)
x = hu6800ENTREZID
mapped_probes = mappedkeys(x)
id_mapping = unlist(as.list(x[mapped_probes]))
lt = functional_enrichment(res, k = 3, id_mapping = id_mapping) # you can check the value of `lt`

# a list of data frames
simplifyGOFromMultipleLists(lt, padj_cutoff = 0.001)

# a list of numeric values
lt2 = lapply(lt, function(x) structure(x$p.adjust, names = x$ID))
simplifyGOFromMultipleLists(lt2, padj_cutoff = 0.001)

# a list of GO IDs
lt3 = lapply(lt, function(x) x$ID[x$p.adjust < 0.001])
```

```
simplifyGOFromMultipleLists(lt3)
```

---

subset\_enrichResult     *Subset method of the enrichResult class*

---

### Description

Subset method of the enrichResult class

### Usage

```
subset_enrichResult(x, i)
```

### Arguments

x                    A enrichResult object from 'clusterProfiler' or other related packages.  
i                    Row indices.

### Value

Still a enrichResult object but with the selected subset of rows.

### Examples

```
# There is no example  
NULL
```

---

term\_similarity         *Similarity between terms based on the overlap of genes*

---

### Description

Similarity between terms based on the overlap of genes

### Usage

```
term_similarity(gl, method = c("kappa", "jaccard", "dice", "overlap"))
```

### Arguments

gl                    A list of genes that are in the terms.  
method                The similarity measurement.

**Details**

The definition of the four similarity measurements can be found at [https://simplifyenrichment.github.io/supplementary/suppl1\\_coefficient\\_definition/suppl1\\_coefficient\\_definition.html](https://simplifyenrichment.github.io/supplementary/suppl1_coefficient_definition/suppl1_coefficient_definition.html).

**Value**

A symmetric matrix.

**Examples**

```
# There is no example  
NULL
```

---

term\_similarity\_from\_enrichResult

*Similarity between terms in the enrichResult class*

---

**Description**

Similarity between terms in the enrichResult class

**Usage**

```
term_similarity_from_enrichResult(x, ...)
```

**Arguments**

x	A enrichResult object from 'clusterProfiler' or other related packages.
...	Pass to <code>term_similarity</code> .

**Details**

The object is normally from the 'clusterProfiler', 'DOSE', 'meshes' or 'ReactomePA' package.

**Value**

A symmetric matrix.

**Examples**

```
# There is no example  
NULL
```

---

`term_similarity_from_gmt`*Similarity between terms from a gmt file*

---

**Description**

Similarity between terms from a gmt file

**Usage**

```
term_similarity_from_gmt(term_id, gmt, extract_term_id = NULL, ...)
```

**Arguments**

<code>term_id</code>	A vector of terms.
<code>gmt</code>	The path of the gmt file.
<code>extract_term_id</code>	If the term ID is contained in the first column only as a substring, setting a function to extract this substring.
<code>...</code>	Pass to <code>term_similarity</code> .

**Value**

A symmetric matrix.

**Examples**

```
# There is no example  
NULL
```

---

`term_similarity_from_KEGG`*Similarity between KEGG terms*

---

**Description**

Similarity between KEGG terms

**Usage**

```
term_similarity_from_KEGG(term_id, ...)
```

**Arguments**

term\_id            A vector of KEGG IDs, e.g., hsa001.  
...                Pass to [term\\_similarity](#).

**Value**

A symmetric matrix.

**Examples**

```
# There is no example  
NULL
```

---

term\_similarity\_from\_MSigDB  
*Similarity between MSigDB terms*

---

**Description**

Similarity between MSigDB terms

**Usage**

```
term_similarity_from_MSigDB(term_id, category = NULL, subcategory = NULL, ...)
```

**Arguments**

term\_id            A vector of MSigDB gene set names.  
category           E.g., 'C1', 'C2', pass to [msigdb](#).  
subcategory        E.g., 'CGP', 'BP', pass to [msigdb](#).  
...                Pass to [term\\_similarity](#).

**Value**

A symmetric matrix.

**Examples**

```
# There is no example  
NULL
```

---

```
term_similarity_from_Reactome
  Similarity between Reactome terms
```

---

**Description**

Similarity between Reactome terms

**Usage**

```
term_similarity_from_Reactome(term_id, ...)
```

**Arguments**

```
term_id      A vector of Reactome IDs.
...          Pass to term\_similarity.
```

**Value**

A symmetric matrix.

**Examples**

```
# There is no example
NULL
```

---

```
widthDetails.word_cloud
  Width for word_cloud grob
```

---

**Description**

Width for word\_cloud grob

**Usage**

```
## S3 method for class 'word_cloud'
widthDetails(x)
```

**Arguments**

```
x            The word_cloud grob returned by word\_cloud\_grob.
```

**Value**

A [unit](#) object.

**Examples**

```
# There is no example
NULL
```

---

word_cloud_grob	<i>A simple grob for the word cloud</i>
-----------------	---

---

**Description**

A simple grob for the word cloud

**Usage**

```
word_cloud_grob(text, fontsize,
  line_space = unit(4, "pt"), word_space = unit(4, "pt"), max_width = unit(80, "mm"),
  col = function(fs) circlize::rand_color(length(fs), luminosity = "dark"),
  test = FALSE)
```

**Arguments**

text	A vector of words.
fontsize	The corresponding font size. With the frequency of the words known, <a href="#">scale_fontsize</a> can be used to linearly interpolate frequencies to font sizes.
line_space	Space between lines. The value can be a <a href="#">unit</a> object or a numeric scalar which is measured in mm.
word_space	Space between words. The value can be a <a href="#">unit</a> object or a numeric scalar which is measured in mm.
max_width	The maximal width of the viewport to put the word cloud. The value can be a <a href="#">unit</a> object or a numeric scalar which is measured in mm. Note this might be larger than the final width of the returned grob object.
col	Colors for the words. The value can be a vector, in numeric or character, which should have the same length as text. Or it is a self-defined function that takes the font size vector as the only argument. The function should return a color vector. See Examples.
test	Internally used. It basically adds borders to the words and the viewport.

**Value**

A [grob](#) object. The width and height of the grob can be get by [grobWidth](#) and [grobHeight](#).

**Examples**

```
# very old R versions do not have strrep() function
if(!exists("strrep")) {
  strrep = function(x, i) paste(rep(x, i), collapse = "")
}
words = sapply(1:30, function(x) strrep(sample(letters, 1), sample(3:10, 1)))
require(grid)
gb = word_cloud_grob(words, fontsize = runif(30, min = 5, max = 30),
  max_width = 100)
grid.newpage(); grid.draw(gb)

# color as a single scalar
gb = word_cloud_grob(words, fontsize = runif(30, min = 5, max = 30),
  max_width = 100, col = 1)
grid.newpage(); grid.draw(gb)

# color as a vector
gb = word_cloud_grob(words, fontsize = runif(30, min = 5, max = 30),
  max_width = 100, col = 1:30)
grid.newpage(); grid.draw(gb)

# color as a function
require(circlize)
col_fun = colorRamp2(c(5, 17, 30), c("blue", "black", "red"))
gb = word_cloud_grob(words, fontsize = runif(30, min = 5, max = 30),
  max_width = 100, col = function(fs) col_fun(fs))
grid.newpage(); grid.draw(gb)
```
